Rexx Reference Manual (TSO)

Rexx is the Restructured Extended Executor Language. New with TSO/E version 2, Rexx is a high-level procedural language that allows programmers to mix instructions with TSO commands, and build high-powered tools and utilities, called "exec"s.

Rexx is a programming language. Rexx is a fascinating language. It is, from my viewpoint, IBM's answer to Basic. It is an English-like interpreted language. No compiler is needed. The computer reads the instructions, one at a time, and if it can interpret it, it will execute it.

The thing that Rexx is best suited for is to create data-manipulation tools, especially for one-time use or for development. Once you learn how to use the language, you can tailor data in ways you never dreamed.

Why learn Rexx? Knowing Rexx can give you a powerful advantage. Being able to manipulate data in esoteric and creative ways can be a tremendous aid to your productivity. Rexx can be very useful for creating and verifying test data, formatting output data, file-integrity-checking, and creating tools that help make your job easier.

A Rexx program can be written far more quickly than one for COBOL or Assembler, for the same task at hand. You wouldn't want to use Rexx in production for high-volume files, though. That's the job of a compiled program. Rexx is for the "quickie", and low-volume tasks.

The reason I decided to write this book, is that with the reference I was using, it took too long to find information that I was looking for. The author of that book knew his stuff, but I felt he had no clue as to what to present, or how to present it. The organization of that book and lack of meaningful examples was frustrating, and simply not acceptable.

This reference discusses Rexx and its use with TSO, as opposed to CMS or personal computers. The intended audience for this book is all levels of mainframe programmers, and "computer-literate" users. You should be at least familiar with TSO, have a TSO UserID, and be able to log on to a mainframe.

I wrote this from the point of view of a Rexx user, and not a teacher. While I was writing this, I envisioned real-life situations that I could find myself in, and I then tried to illustrate the best way to handle it. The examples were not written for the sake of example; they were written to show *how* to solve a given problem. I added many examples from my real-life work experience. These are execs that I used to solve real problems.

So it is my hope that this reference is easy to use, has useful and pertinent examples, and can help you get your job done. This manual is the quickest way to get up, running, and productive in Rexx. All of the examples in this book have been tested on an IBM mainframe, on Rexx370 Vers 3.48 01 May, 1992. Any errors resulting in the use of these examples would probably then be due to environmental differences, or the transfer of the example from this document.

If there is something about this book that really bugs you, or really pleases you, or if you have any other comments, criticisms, or suggestions, please feel free to e-mail me at: dgrundsr@earthlink.net.

This book is divided into five sections.

The first section is a reference, for the experienced programmer. I put this section first because I feel that this will be the one that is used the most. With this format, you don't have to worry about whether a Rexx component is a function, instruction, or anything else. Just flip through the alphabetically-sorted reference, find the keyword, read, and use!

The second section of this book is a short Rexx tutorial. This is where the beginner should start.

The third section of this book will be examples: *useful* examples.

The fourth section of this book will be on the Rexx environment: how to establish and maintain it, and how to use it alone, and in conjunction with ISPF.

The fifth section of this book, the appendix, contains lists of instructions by class, and other Rexx references.

Section I - Reference

General Rules

Form:	The Rexx language is generally free-form. You can put any number of spaces between instructions, operands, etc.
	The elements of a Rexx exec are: Rexx instructions, Rexx functions, TSO external functions, and TSO commands.
	There elements generally end at the end of a line or at the beginning of a comment, whichever comes first. They can be stacked on the same line if separated by semi-colons.
First Line:	A Rexx exec is identified by the character string "REXX" (no quotation marks) in the first line of the exec. Generally, it is recommended to start a Rexx exec off with a comment stating the name, short description, and "REXX" keyword, as follows: /* MyFirst - MyFirst Rexx Program */ or /* Calcl - My Calculator Rexx */

Rexx is also case-insensitive. Use upper- or lower-case letters at your discretion. Note, however, that some functions look at the case of letters!

All values that appear in Rexx statements are translated to upper case unless they are enclosed in matching apostrophes or quotation marks.

In some cases, not all of the operands of an instruction are discussed. There are some operands that are highly esoteric, that I feel will be needed only in extremely specific situations. The appendix contains information on additional Rexx reference material.

Abbrev

Purpose:	Return a 1 (TRUE) or zero (FALSE) based on the test that a word begins in a certain string. It is a subtle variation of the LEFT function.
Type:	Rexx Function
Syntax:	Result = ABBREV(word, string, length)
Usage:	If the first <i>length</i> characters of <i>word</i> = <i>string</i> , then <i>result</i> will be TRUE.
Examples:	<i>Result</i> = ABBREV("America","Am",2) /* TRUE; <i>Result</i> = 1 */
	Result = ABBREV("America","mer",3) /* FALSE; <i>Result</i> = 0 */

Abs

Purpose: Return the absolute value of a number: drop the sign, and format according to the current setting of NUMERIC DIGITS.

Type: Rexx Function

Syntax: *NewNum* = ABS(*OldNum*)

Example: NewNum = ABS(-436) NewNum will be 436.

Address

Purpose:	Return or change the setting of the environment that is currently receiving commands
Туре:	Rexx Function and Rexx Instruction
Syntax:	1) Address Environ string(instruction)2) Environ = Address()(function)
Usage:	 Rexx passes to the environment any strings that are enclosed in quotation marks (or apostrophes), or any that it does not know what to do with. 1) The instruction form sets the environment that will receive these strings that are fed through by Rexx. This setting is "permanent" (for the duration of the current exec), unless it is supplied on the same line. If it is, then the setting that is specified is valid <i>only for the string on that line</i>. Rexx doesn't care what you set the environment to at the time you use this instruction. There is no validation at this point. The default is "TSO". 2) The function form simply returns the current environment setting
See Also:	SubCom
Example 1:	The following Rexx exec illustrates the use of the Address function and the Address instruction. Say "Environ = " Address() Address TSO Say "Environ = " Address() Address ISPEXEC Say "Environ = " Address() Address MVS Say "Environ = " Address() Address Junk Say "Environ = " Address() Address Dave Say "Environ = " Address() Will display: Environ = TSO Environ = TSO Environ = ISPEXEC Environ = JUNK Environ = JUNK Environ = DAVE

Example 2: The following Rexx exec illustrates the *effects* of the use of Address:

```
1 "Browse Dataset(Rexx.Exec) "
2 address ispexec
3 "Browse Dataset(Rexx.Exec) "
4 address ispexec "Edit Dataset(Rexx.Exec) "
```

Explanation of the above exec:

1 This is a character string that Rexx does not understand, so Rexx passes it to the environment. Since the environment was not set, it remains as "TSO". TSO, in turn, does not know what to do with this character string, so the following displays:

```
COMMAND BROWSE NOT FOUND

3 *-* "Browse Dataset(Rexx.Exec) "

+++ RC(-3) +++
```

2 Rexx now sets the environment to "ISPEXEC" (the name for ISPF's environment).

3 ISPF receives this character string, and knows what to do with it, so it opens the dataset called "Rexx.Exec" for Browse.

4 This line is setting the environment at the same time as sending the string. ISPF then edits a dataset called "Rexx.Exec".

Example 3: This exec demonstrates the "temporary" environment setting.

```
1 address TSO
```

```
2 address ispexec "Edit Dataset(Rexx.Exec) "
```

```
3 "Browse Dataset(Rexx.Exec) "
```

```
4 address ISPEXEC
5 "Edit Dataset(Rexx.Exec) "
```

In the above exec,

Line 1 sets the environment to "TSO"

Line 2 will edit "Rexx.Exec", having set the environment temporarily to ISPEXEC.

Line 3 will err, because TSO does not recognize the command: ${\tt COMMAND\ BROWSE\ NOT\ FOUND}$

```
5 *-* "Browse Dataset(Rexx.Exec) "
+++ RC(-3) +++
```

Line 4 will set the environment to ISPF

Line 5 will edit the dataset successfully.

Apostrophes

Purpose: To enclose a literal (character string).

See "Quotation Marks/Apostrophes" for documentation on this function.

Arg

Purpose: Retrieve data from the TSO command line.

Type: Rexx Function and Rexx instruction

See "Parse" for documentation on this function.

Assignment Statement

Purpose:	e	variable. The value you assign to the variable can be umber, hex, binary, etc.
Syntax:	up to 250 you would Value Format The represe	of the variable being assigned. It can be characters long, but I don't know why I want to do that to anyone. The value that you are assigning to the variable sentation of the value. The default is Valid values are "X" for hexadecimal,
Examples:	A = 1 B = "F1F2F3F4"x C = '11110010'B	assigns the value '1' to the variable 'A' assigns the value '1234' to variable 'B' assigns the value '2' (X'F2') to C

BitAnd

Purpose:	Return a string that is the result of two strings that were logically AND'd together.
Type:	Rexx Function
Syntax:	Result = BitAnd(<i>string1</i> , <i>string2</i> , <i>padString</i>) String1 and String2 are the strings used in the AND operation. <i>padString</i> is a string used for padding
Usage:	To AND two strings is to multiply the bits of one string to the corresponding bits of the other string, and return the result. In English, it reads, "If the bit of the first string AND the corresponding bit of the second string are both on, then the resulting bit will be on. Otherwise, the resulting bit will be off."
	<i>padString</i> is used to fill the shorter of the two strings (on the right) so the strings are the same length when being processed. If no padString is supplied, the operation works only for the length of the smaller string.
	The sole purpose this function has is to do bit-level manipulation.
	This function is the opposite of BitOr.
Example 1	The following example will convert a one-character reply from upper-case to lower case, by virtue of turning off bit 1: ResultString = BitAnd('Y','10111111'B) Say ResultString
	The upper case 'Y' is X'E8', or B'11101000'. The lower case 'y' is X'A8', or B'10101000'.
Example 2	The following example will convert all letters of a string to lower case (taking the above example a step further). Sentence = "The Quick Brown Fox Jumps Over The Lazy White Dog" ResultString = BitAnd(Sentence, '10111111'B, '10111111'B)
Example 3	The following example does the exact same thing. Sentence = "The Quick Brown Fox Jumps Over The Lazy White Dog" ResultString = BitAnd(Sentence,'BF'X,'BF'X)
	Notice that the coding in this example is a little shorter, but not as clear to the reader: a binary 10111111 equals a hexadecimal BF. I prefer example 2 to example 3 because it is clearer.

BitOr

Purpose:	Return a string that is the result of two strings that were logically OR'd together.
Type:	Rexx Function
Syntax:	Result = BitOr(<i>string1</i> , <i>string2</i> , <i>padString</i>) String1 and String2 are the strings used in the OR operation. padString is a string used for padding
Usage:	To OR two strings is to add the bits of one string to the corresponding bits of the other string (with no carry), and return the result. In English, it reads, "If either the bit of the first string OR the corresponding bit of the second string are on, then the resulting bit will be on. Otherwise, the resulting bit will be off."
	<i>padString</i> is used to fill the shorter of the two strings (on the right) so the strings are the same length when being processed. If no padString is supplied, the operation works only for the length of the smaller string.
	The sole purpose this function has is to do bit-level manipulation.
	This function is the opposite of BitAnd.
Example 1	The following example will convert a one-character reply from lower-case to upper case, by virtue of turning on bit 1: ResultString = BitOr('y','01000000'B)
	The lower case 'y' is X'A8', or B'10101000'. The upper case 'Y' is X'E8', or B'11101000'.
Example 2	The following example will convert all letters of a string to upper case (taking the above example a step further). Sentence = "The Quick Brown Fox Jumps Over The Lazy White Dog" ResultString = BitOr(Sentence,,'01000000'B) String2 is padded to the length of Sentence with binary '01000000'.
Example 3	The following example does the exact same thing. Sentence = "The Quick Brown Fox Jumps Over The Lazy White Dog" ResultString = BitOr(Sentence,,'40'X) Notice that the coding in this example is a little shorter, but not as clear to the reader: a binary 01000000 equals a hexadecimal 40. I prefer example 2 to example 3 because it is clearer.

BitXOr

Purpose:	Return a string that is the result of two strings that were logically XOR'd together.
Type:	Rexx Function
Syntax:	Result = BitXOr(<i>string1</i> , <i>string2</i> , <i>padString</i>) <i>String1</i> and <i>String2</i> are the strings used in the AND operation. <i>padString</i> is a string used for padding
Usage:	To XOR two strings is to compare the bits of one string to the corresponding bits of the other string, one, by one, and return the result of the compare. In English, it reads, "If the bit of the first string AND the corresponding bit of the second string are the same, then the resulting bit will be off. Otherwise, the resulting bit will be turned on.
	<i>padString</i> is used to fill the shorter of the two strings (on the right) so the strings are the same length when being processed. If no <i>padString</i> is supplied, the operation works only for the length of the smaller string.
	If you XOR something to itself, the result will be hex zeroes.
	The sole purpose this function has is to do bit-level manipulation.
	You can use this instruction to do some rudimentary character-string encryption. See the example below.
Example 1	The following example will demonstrate the effect of this function. ResultString = BitXOr('11111111'B,'01010101'B) Say C2X(ResultString)
	String1:11111111String2:01010101Result:10101010 (X'AA')
Example 2	This example will further demonstrate the effect of this function. ResultString = BitXOr('10101010'B,'01010101'B) Say C2X(ResultString)
	String1:10101010String2:01010101Result:11111111 (X'FF)'

Example 3 This example demonstrates how to encrypt a character string. Use the
exact same instruction to decrypt it.
Sentence = "The quick brown fox jumps over the lazy white
dog"
Say Sentence
Sentence = BitXOr(Sentence,,'BF'X)
Say Sentence
Sentence = BitXOr(Sentence,,'BF'X)
Say Sentence

Displays:

B2X

Purpose:	Convert a binary string to a hexadecimal representation
Type:	Rexx Function
Syntax:	<i>Result</i> = B2X(<i>binarystring</i>) <i>Result</i> is the hexadecimal representation of <i>binarystring</i> , which is a string

Usage: Convert a binary to a hexadecimal number

of zeroes and ones.

The following exec: Say "B2X('11101111')=" B2X('11101111') Example 1

Will display the following: B2X('11101111') = EF

Call

Purpose:	To invoke, or transfer control to a subroutine or program, expecting to come back.
Type:	Rexx Instruction
Syntax:	Call subroutine Call program
Usage:	A Call is used to facilitate structured programming. It is widely used to break the mainline processing up into blocks of code that are referenced by the mainline section. A lot of the examples illustrate structured programming and the use of Calls.
	To call a Rexx exec or Clist <i>implicitely</i> , simply issue an "Address TSO" command, followed by the name of the Rexx exec or Clist, on separate lines.
Example:	Call Proc01 /* Call program section 1 */
	Proc01: {code} {code} Return
	The following code snippet is part of an exec that compares two disk files: "Address TSO" "Call 'SYS1.LINKLIB(IEBCOMPR)'" If RC = 0 then Say "The modules are identical"

Call On

Purpose:	Establish a subroutine to handle an error condition
Type:	Rexx Instruction
Syntax:	Call On condition
	See "Trapping Errors" in the Environment section of this manual for a discussion of this instruction.

Center/Centre

Purpose:	To center a string within a larger string
Type:	Rexx Function
Syntax:	Center(<i>string</i> , <i>length</i> , <i>pad</i>)
Usage:	Center <i>string</i> within a larger string of <i>length</i> characters. If <i>pad</i> is present, it will be used as the pad character. If it is not, spaces will be used.
	This function can be specified as either "Center" or "Centre".
Example:	The following excerpt of a Rexx Exec Heading = "Tuesday" Field = Center(heading, 30, '-') Say Field
	will result in

Clist

Purpose: Run a TSO command list the "old" way. This is what was used to accomplish the functions that Rexx Execs accomplish today.

Clists are mentioned here only because of their history and effect on today's Rexx language. I am in no way advocating using them. Anything you could do with a Clist can be accomplished with a Rexx exec, and usually cleaner.

Clists and Rexx execs alike are typically stored in a PDS (partitioned dataset). A Clist library is allocated to the DDName SYSPROC, while a Rexx exec library is allocated to the DDName SYSEXEC.

Comma

Purpose: To continue a Rexx statement
Example: The following Rexx Exec:
 /* T1 - Example Rexx Program */
 JanuarySales = 100
 FebruarySales = 150
 MarchSales = 5
 AprilSales = 15
 MaySales = 10
 Total = JanuarySales + FebruarySales + ,
 MarchSales + AprilSales + MaySales
 Say 'The total sales = ' Total
 will produce the result "280". Notice the continuation comma after
 FebruarySales.

Comments

Purpose:	To document an exec, or annotate the lines within.
Syntax:	Start with /* and with */. They can span any number of lines, but cannot be nested (supplied within another set).
Usage:	Typically, you would comment each block of code with a comment line preceding that block of code. If you wish to comment one particular line, code the comment to the right of that line.
Example: Say "	/* This is a Rexx comment */ Hello, World" /* This is also a Rexx comment */

A = 1	/* Set the value of A to 1
B = 2	/* Set the value of B to 2 */
/* C = 3 */	/* This instr was commented out */
D = 4	/* Set the value of D to 4 $*/$

Compare

Purpose:	Compare two strings
Type:	Rexx Function
Syntax:	Result = COMPARE(string1,string2,pad)
Usage:	Compare two strings, and return the number of the position where the inequality between the two strings starts. If the strings are equal, there is no inequality, and so the function returns a zero.
	When one string is shorter than the other, it is first padded on the right with the pad character. The default pad character is a space.
	Characters within quotation marks are treated with respect to their case. An upper-case letter will not equal a lower-case one.
Example:	Result = COMPARE("Apples","Oranges") Say Result Will yield 1, because the first position is unequal.
	Result = COMPARE("Apples", "Apple") Say Result Will yield 6, because the sixth position of the first string, "s", is unequal to the sixth position of the second string, which was padded to a blank.
	Result = COMPARE("Apples", "Apples") Say Result Will yield 0, because the strings after padding are identical.
	Result = Compare("Applessssssss", "Apples", "s") Say Result Will yield 0, because the strings after padding are identical.

Comparison Operators

REXX comparison operations resolve to a 1 if the result of the comparison is true, and a 0 if the result of the comparison is false. REXX also uses an equality concept called 'strictly equal'.

Two values are 'strictly equal' if they match exactly, including imbedded blanks and the case of letters. Two values are 'equal' if they don't match exactly, but they resolve to the same quantity after REXX substitution and evaluation.

The following comparison operators can be used in REXX expressions:

- == strictly equal
- = equal
- = not strictly equal (can also use not sign, X'5F')
- \downarrow not equal (can also use not sign, X'5F')
- > greater than
- < less than
- >< greater than or less than (same as not equal)
- >= greater than or equal to
- <= less than or equal to
- \setminus not less than
- \geq no greater than

REXX Comparison Operators Order of Precedence:

- \ (not)
- $\|$ concatenation
- & AND
- | && logical OR and EXCLUSIVE OR

Concatenation

Purpose: To combine two or more strings or literals into one variable. One way concatenation is achieved by the use of "Or" bars. These are the vertical bars that can be found on the keyboard to the right of the +/= key. This is the preferred way, since it is *explicit*. If you use this method, all blanks between the two values that are being concatenated will be suppressed. If you want spaces between your variables, you must concatenate them as well. See example 1 below. Another way to achieve concatenation is to simply put two variables of different types next to each other (juxtaposition). (Note that juxtaposition is accomplished by simply not using the "or" bars). Two or more intervening blanks will be compressed down to one. Again, if you want spaces between your variables, you must concatenate them as well. See example 2 below. In summary, us the "Or" bars if you wish to strip out all intervening spaces. Use juxtaposition if you wish to keep just 1. Examples using "Or" bars: Say "Example 1" "Hello World" Say "Example 1" || "Hello World" Say "Example 1"||"Hello World" All of the above will result in the same thing: Example 1Hello World Notice that all intervening spaces were removed by Rexx. Say "Example 1" || " " || "Hello World" will result in: Example 1 Hello World Notice the intervening space (between "1" and "Hello"). Examples using juxtaposition: Say "Example 2" "Hello World" Notice that in this example, there is no legitimate concatenation. The quotation marks intended to define literals (variables of the same type). Instead, Rexx interpreted this as one string, and by its rules, translated two quotation marks into one. Say "Example 2" "Hello World" "Hello World" Say "Example 2" Both of the above examples will result in:

Example 2 Hello World

Condition

Purpose:	Retrieve the setting information for the currently trapped REXX condition.
Type:	Rexx Function
Syntax:	 String = CONDITION('code') String is the returned setting. Code is supplied to request the type of information. The default is I. Codes: C- Return the name of the current condition D- Return the descriptive string associated with the condition I- Return the name of the actual instruction that was executing when the condition occurred S- Return the status of the condition trap. This will be either ON, OFF, or DELAY.
Usage:	This function is used in error trapping.
Example:	<pre>In the following exec, we try to add Increase to Salary, neither of which has been defined: Signal On NoValue Salary = Salary + Increase Say "My salary = " Salary exit NoValue: Say "Undefined variable on line" SIGL Say "The current trapped condition is" condition("C") Say "The variable is" condition("D") Say "The variable is" condition("D") Say "The name of the instruction is" condition("I") Say "The instruction is:" sourceline(SIGL) Say "The instruction is:" sourceline(SIGL) Say "The status of the condition trap is" condition("S")</pre>

Continuation

Purpose: To code an instruction that requires more than one line.

Syntax: Instructions are continued with a comma.

See **Comma** for documentation on this subject.

Copies

Purpose:	Copies a string to itself a specified number of times.
Type:	Rexx Function
Syntax:	<i>Result</i> = COPIES(<i>string</i> , <i>quantity</i>)
Usage:	Set result to quantity sets of string.
Example:	Line = COPIES('*',75) Will result in the variable "Line" containing 75 asterisks.

C2D

Purpose:	Convert a string to its decimal equivalent
Type:	Rexx Function
Syntax:	Result = C2D(string)
Usage:	Internally, the function first converts the string to its hexadecimal equivalent. Then it converts that hexadecimal value to decimal. It is the inverse of D2C.
Example:	result = C2D(" ") /* Two spaces */ After execution of the previous instruction, <i>result</i> will contain 16448, the decimal representation of X'4040'
	result = C2D("6") <i>result</i> will contain 246, the decimal representation of X'F6'

C2X

Purpose:	Convert a string to its hexadecimal equivalent		
Type:	Rexx Function		
Syntax:	Result = C2X(string)		
Example:	result = C2X(" ") /* Two spaces */ result will contain 4040		
	result = C2D("6") result will contain F6		

DataType

- Purpose: This is a Rexx built-in function that will allow you to test to see the type of data a variable contains. There are two forms of this function.
- Type: Rexx Function
- Syntax 1: *Result* = DATATYPE(*string*) If *string* was a number, *result* would contain "NUM". Otherwise, it would contain "CHAR".
- Syntax 2:Result = DATATYPE(string,type)Using this form, result will contain a one (TRUE) if string corresponds to
type. Otherwise, it will contain a zero (FALSE).

Types:				
Type	Description			
А	Alphanumeric: A-Z, a-z, 0-9			
В	Binary: 0 or 1 only			
D	Double-byte character set			
L	Lower-case letters			
Μ	Mixed-case letters			
Ν	Number			
S	Symbol: valid Rexx symbol			
U	Uppercase letters			
W	Whole number			
Х	Hexadecimal number: 0-9, A-F			

Examples: The following excerpt: If datatype("Dave",M) then Say "Dave is mixed case" else Say "Dave is not mixed case" will display: Dave is mixed case

Date

Purpose:	This is a REXX built-in function that will provide you with the current date, in a variety of different formats.		
Type:	Rexx Function		
Syntax:	Result = DATE(option) Based on the specification of the Options below, "result" will contain the date in the corresponding format, if the current date was April 8, 1997:		

Usage: see the chart below

Option	Meaning	Format	Example
(blank)	European	dd Mmm yyyy	8 Apr 1997
Ν			
В	Basedate: Number of complete days	nnnnn	729121
	since January 1, of the year 1.		
С	Century: Number of days in this century	nnnnn	35527
D	Days: Number of days so far this year	nnn	98
Е	European	dd/mm/yy	08/04/97
J	Julian date	yyddd	97098
М	Name of the current month	Mmmmmmm	April
0	Ordered, suitable for sorting	yy/mm/dd	97/04/08
S	Ordered, suitable for sorting	yyyymmdd	19970408
U	USA format	mm/dd/yy	04/08/97
W	Name of current weekday	Ddddddd	Tuesday

option is not case sensitive. You can use either upper or lower case.

Examples: If today was April 8, 1997: Today's date is date() will yield: Today's date is 8 Apr 1997 Today is Date(M) will yield: Today is April

DelStack

Purpose: To delete the most recently-created TSO stack in preparation for use of it.

Type: TSO Command

Syntax: DELSTACK

Usage: Use this instruction right before you begin adding items to the TSO stack. This ensures that you don't inadvertently process data that was left on the stack by a previous program.

This is typically used in conjunction with the (Parse) Pull instruction.

DelStr

Purpose:	Delete characters from a string			
Type:	Rexx Function			
Syntax:	Newstring = DELSTR(string, start, length)			
Usage:	Remove characters from <i>string</i> starting with position <i>start</i> , and for a length of <i>length</i> . The resulting string will be placed in <i>newstring</i> . The default for length is the entire remainder of the string.			
Example:				

Result = DELSTR("ABCDEFGHIJKLMNOPQRSTUVWXYZ",3,20)

After execution of this instruction, result will contain "ABWXYZ".

DelWord

Purpose:	Delete words from a string		
Type:	Rexx Function		
Syntax:	<i>Newstring</i> = DELWORD(<i>string</i> , <i>start</i> , <i>quantity</i>)		
Usage:	Remove <i>quantity</i> words from <i>string</i> starting with word number <i>start</i> . The resulting string will be placed in <i>newstring</i> .		
Example:			

Result = DELWORD("FourScore and seven years ago, our fathers ",3,4) After execution of this instruction, *result* will contain "FourScore and fathers".

Digits

Purpose: Specify the number of digits that Rexx carries in arithmetic operations (precision).

- Type: Rexx Function
- Syntax: Numeric Digits n

See Numeric Digits for documentation on this function.

Do

Purpose:	Execute a set of instructions, either under the control of a counter variable,
	or based upon current program conditions.

- Type: Rexx Instruction
- Syntax: DO expression variable=start TO limit BY increment WHILE expression UNTIL expression FOREVER (one or more statements to execute) END variable
- Usage: There are several formats of the DO instruction. Each of the operands of the DO instruction as illustrated above are optional.

For the sake of explanation, the instructions in between the DO and END are commonly referred to as a DO Group.

If no operands are supplied, then the instructions in the DO Group are executed **one time**.

expression Any valid REXX expression, but it must resolve to a positive whole number. DO 19 DO I = 19 (one or more instructions) END End End

Both of the above examples would execute the instructions 19 times.

variable=start TO limit BY increment

> Choose a control variable, and assign it a start value. This control variable is incremented by the BY amount on each iteration of the loop. The loop will stop when the control variable reaches the limit. Do I = 1 TO UpperLimit BY 1 (one or more instructions)

End

In the above example, I is the control variable. It starts with a value of 1, and the loop continues until I = UpperLimit.

BY can be a negative number if UpperLimit starts out to be less than the control variable.

WHILE expression

UNTIL expression

Continue to perform the instructions WHILE or UNTIL the expression is true. WHILE and UNTIL have opposite connotations. WHILE will test for a true condition *before* the do group is executed. UNTIL will test for a true condition *at the end of* the do group. Using UNTIL assures you that the do group will execute at least one time.

```
Times = 1
StillIn = 'Y'
Do While StillIn = 'Y'
    Say "I am working on iteration number "Times
    Times = Times + 1
    If Times > 5 then StillIn = 'N'
End
Times = 1
StillIn = 'Y'
Do Until StillIn = 'N'
    Say "I am working on iteration number "Times
    Times = Times + 1
    If Times > 5 then StillIn = 'N'
End
```

The two examples above will produce identical results:

I am working on iteration number 1 I am working on iteration number 2 I am working on iteration number 3 I am working on iteration number 4 I am working on iteration number 5

Notice, however, that the only difference between the two examples is the expression following the conjunction (WHILE/UNTIL)

If you are in doubt as to which conjuntion to use, then apply the KIS principle (Keep It Simple). Use the one that makes the code easier to understand.

FOREVER Execute the do group continuously, until "told" to stop.

```
END Variable
```

A control variable name can be supplied to an END statement to clarify which DO group the END statement refers to.

```
Do I = 1 to 4
Do J = 1 to 13
(one or more instructions)
End J
End I
```

Examples:

```
Do I = 1 to 25
                    Say "Hello, world!"
             End
             The above example will print the message Hello World! 25 times.
             Do I = 1 to 0
                  Say "Hello, world!"
             End
             The above example will print nothing, because 0 < 1.
             Do I = 1 to 10 by 2
                    Say "Hello World #"I
             End
             The above example will print:
             Hello World #1
             Hello World #3
             Hello World #5
             Hello World #7
             Hello World #9
             Do I = 1 to 100 by 2 for 5
                    Say "Hello World #"I
             End
             The above example will print:
             Hello World #1
             Hello World #3
             Hello World #5
             Hello World #7
             Hello World #9
             (Only five iterations)
             /* Test1 - Example Rexx Program - Rexx EXEC */
             Do Forever
               Say "Tell me your name, or enter 0 to quit"
               Pull Answer
               If Answer = "0" then Leave
               Say "You told me that your name was" Answer"
             End
             The above Rexx exec will echo back whatever you type in, until you enter
             a zero :
             You told me that your name was HOMER SIMPSON
Caution:
             Here is a common trap. After a do group completes, your index variable
             will be one higher than the limit. In the following example, assume you are
             traversing an array of records that you read in from a disk file, and that the
             disk file contained 114 records.
             Do CurrRecNO = 1 to IPRec.0
                    (processing...)
             End
```

At this point, CurrRecNO will contain 115, and not 114.

Drop

Purpose: "Unassign" a variable. This, in effect, converts a variable name to a literal (in upper case).

Type: Rexx Instruction

Example: The following excerpt from a Rexx exec: Greeting = "Merry Christmas" Say Greeting Drop Greeting Say Greeting

> Will yield the following results: Merry Christmas GREETING

D2C

Purpose:	Convert a decimal number to a character.			
Type:	Rexx Function			
Syntax:	Result = D2C(number, length)			
Usage:	Convert the decimal number to its internal hexadecimal format. It is the inverse of C2D. <i>Number</i> must be a whole number or a variable containing a whole number. It must also be non-negative, unless <i>length</i> is specified. <i>Length</i> is the length of the result, and is optional. If <i>Length</i> is not specified, <i>Result</i> will be left-zero-suppressed. If <i>Number</i> is negative, then <i>Length</i> is required.			
Example:	The expression Say D2C(240) Say D2C(240,5) Say D2C(80)	displays 0 (X'F0') 0 (right justified in a 5- byte field) & (X'50')		

D2X

Purpose:	Convert a decimal number to a hexadecimal value.			
Type:	Rexx Function			
Syntax:	Result = $D2X(number, length)$			
Usage:	Convert a decimal number to its hexadecimal representation. It is the inverse of X2D. Length- Length of the final result, in characters (optional)			
Example:	The expression Say D2X(240) Say D2C(80)	displays F0 50		

End

Purpose: Terminate a "DO" loop or block.

See the documentation on **Do** for more detailed information.

ErrorText

Purpose:	This is a REXX built-in function that will return the English language text for an error code.
Type:	Rexx Function
Syntax:	Say ErrorText(RC) where RC is the error code. Error codes are set by all Rexx errors.

Usage: To report back to the user, in English, what the problem is.

Example:

```
/* Test1 - Example Rexx Program -
                                     Rexx EXEC */
Do I = 1 to 20
    Say "Error "I" is "errortext(I)
End
The above Rexx exec will display the following output:
Error 1 is
Error 2 is
Error 3 is Program is unreadable
Error 4 is Program interrupted
Error 5 is Machine storage exhausted
Error 6 is Unmatched "/*" or quote
Error 7 is WHEN or OTHERWISE expected
Error 8 is Unexpected THEN or ELSE
Error 9 is Unexpected WHEN or OTHERWISE
Error 10 is Unexpected or unmatched END
Error 11 is Control stack full
Error 12 is Clause too long
Error 13 is Invalid character in program
Error 14 is Incomplete DO/SELECT/IF
Error 15 is Invalid hexadecimal or binary string
Error 16 is Label not found
Error 17 is Unexpected PROCEDURE
Error 18 is THEN expected
Error 19 is String or symbol expected
Error 20 is Symbol expected
```

ExecIO

Purpose:	Perfo	Perform input/output operations.		
Type:	TSO	Command		
Syntax: whe		ECIO quantity operation ddname seq (options"		
qua	quantity represents the number of records to read or write operation DiskR for "read from disk" DiskW for "write to disk" DiskRU for "read for update"			
<i>ddname</i> The ddname of the file for which I/O is to be performed. The file must be allocated by TSO prior to its use.		The ddname of the file for which I/O is to be performed. The file must be allocated by TSO prior to its use.		
<i>seq</i> Sequence number of the desired record, for disk read				
optionsSTEM stem. FINISSTEM is specified when reading records from or writing an array. stem is the "name" of the array. If STEM is not a		STEM <i>stem.</i> FINIS STEM is specified when reading records from or writing records to an array. <i>stem</i> is the "name" of the array. If STEM is not specified, operations are performed on a disk file instead of an array.		

Usage: If you perform a disk read operation, and you reach end-of-file, RC will be set to a 2.

Examples:				
Read	Write	Ex #	Comments	
Disk	TSO Stack	1	Read a disk file into the TSO stack	
Disk	Array	2	Read a disk file into an array	
TSO Stack	Array	3	Read the TSO stack into an array	
TSO Stack	Disk	4	Read the TSO stack, write a disk file	
Array	Disk	5	Read an array, write a disk file	
Array	TSO Stack	6	Read an array into the TSO stack	
Disk	Disk	N/A	Read one disk file; write another:	
			1) Read disk file into array	
			2) Write array to disk file	
Disk	Disk	7	Copy a disk file, one record at a time	
Disk	Disk	8	Disk update (update a record in place)	
Array	Array	9	Copy one array to another	
TSO Stack	TSO Stack	N/A	(Only one TSO stack is available)	

Examples:

```
Example 1: Read a disk file into the TSO stack

"Alloc fi(DDIn) Da(user.work) shr"

NewStack

"ExecIO * DiskR DDIn (Finis "

"Free Fi(DDIn)"

And then, to process the stack:

Do while queued() > 0

Pull OneLine

Say OneLine
```

End

Caution: If you read information into the stack, and then leave it there, whether intentionally or by an error in your Rexx exec, TSO will try to execute it.

Example 2: Read a disk file into an array

```
"Alloc fi(DDIn) Da(Rexx.exec(TestData)) shr"
"ExecIO * DiskR DDIn (Stem Lines. Finis "
"Free Fi(DDIn)"
And then, to process the array:
Say "The disk file contains " Lines.0 "lines. Here they
are:"
Do I = 1 to Lines.0
    Say Lines.I
End
```

```
End
```

```
Example 3: Read the TSO stack into an array
```

```
/* If the queue is empty, say so and get out */
If queued() < 1 then do
    say "The TSO stack is empty!"
    Exit 16
End
/* Now read the stack into an array */
Lines.0 = queued()
Do I = 1 to queued()
    Pull NewLine
    Lines.I = NewLine
End
And then, to process the array:
Do I = 1 to Lines.0
    Say Lines.I
End</pre>
```

Example 4: Write the TSO stack to disk

```
If queued() > 0 then do
   "Alloc Fi(DDOut) da(work.data(test2)) shr"
   "ExecIO * DiskW DDOut (Finis "
   "Free Fi(DDOut)"
End
Else
   Say "The queue was empty; no file written!"
```

Example 5: Write an array to disk

```
"Alloc Fi(DDOut) da(work.data(test3)) shr"
"ExecIO * DiskW DDOut (Stem Recds. Finis "
"Free Fi(DDOut)"
```

Example 6: Read an array into the TSO stack

```
"Alloc Fi(DDIn) da(work.data(test1)) shr"
"ExecIO * DiskR DDIn (Finis "
"Free Fi(DDIn)"
Say "I read "queued()" records into the TSO stack"
DelStack /* Delete this stack when done */
```

Example 7: Copy a disk file, one record at a time

```
"Alloc Fi(DDIn) da(work.data(test1)) shr"
"Alloc Fi(DDOut) da(work.data(test6)) shr"
RecsCopied = 0
Do Forever
    "ExecIO 1 DiskR DDIn"
                                         /* Read a disk record*/
                                         /* Not end of file */
    If RC = 0 then do
         "ExecIO 1 DiskW DDOut" /* Write a disk rec */
        RecsCopied = RecsCopied + 1 /* Count the records copied */
    End
    Else Do
                                         /* End of file
                                                                 * /
         "ExecIO 0 DiskR DDIn (Finis" /* Close the input file
"ExecIO 0 DiskW DDOut (Finis" /* Close the output file
                                                                         */
                                                                         * /
        Leave
    End
End
"Free Fi(DDIn,DDOut)"
Say "I copied "RecsCopied" records"
```

Example 8: Disk Update (update a record in place)

This is accomplished by reading a disk record (for update) into the stack, removing it from the stack into a variable, modifying it (in the variable), putting it back into the stack, and then writing the record back to disk, from the stack.

```
"Alloc Fi(DDUp) da(work.data(test1)) OLD"
"NewStack"
                                       /* Establish a new stack
                                                                    */
RecsUpdated = 0
                                       /* Read record number 4
"ExecIO 1 DiskRU DDUp 4 "
                                                                    * /
Pull Record
                                       /* Read stack
                                                                    * /
Say "Record number 4 is" Record
Record = left(Record,10) || "* this asterisk is in column 11"
Say "The record was changed to:" Record
Push Record
                                       /* Put it back into the stack*/
                                       /* Write the record back
"ExecIO 1 DiskW DDUp
                                                                   */
RecsUpdated = RecsUpdated + 1
"ExecIO 0 DiskW DDUp (Finis"
                                       /* Close the I/O file
                                                                    */
"Free Fi(DDUp)"
"DelStack"
                                       /* Delete the new stack
                                                                    */
Say "I updated "RecsUpdated" records"
```

Example 9: Copy one array to another

```
"Alloc Fi(DDin) da(work.data(test1)) SHR"
RecsCopied = 0
"ExecIO * DiskR DDin (stem Recs. Finis)" /* Read the disk into array */
Say "There are "Recs.0" records in the Recs array"
"Free fi(DDIn)"
Do I = 1 to Recs.0
```

```
Recs2.I = Recs.I
End
Recs2.0 = Recs.0
Say "There are "Recs2.0" records in the Recs2 array"
Do I = 1 to Recs2.0
    Say Recs2.I
End
```

Exit

Purpose:	Terminate a Rexx exec, and optionally set a return code.
Type:	Rexx Instruction
Syntax:	Exit <i>ReturnCode</i> where <i>ReturnCode</i> is any code you wish to set.
Usage:	Typically, the Exit instruction is coded at the end of a Rexx exec's processing, but it can indeed be used to prematurely terminate a Rexx exec. <i>ReturnCode</i> is the MVS return code, and can be tested by a calling program (another Rexx exec, for example), or by JCL.
	To check for charcter strings instead of words, use Index.
Example:	Exit 16 /* Tell the caller I failed */ Exit 0 /* Tell the caller I processed ok */

Expose

Purpose:	Make a local variable available to an external routine
Syntax:	PROCEDURE EXPOSE variable
Usage:	Typically, when an exec calls a procedure, it passes to the procedure all of the necessary values. The procedure, by rules of good coding, hides all of its local variables (by using the "Procedure" statement. If the procedure wants to pass one of those variables back, it can simply "Expose" the variable.
Example:	This is an example of a program that will calculate a bowling average for a five-game tournament. /* Test1 - Example Rexx Program */ Call GA 157 202 170 160 144 Say "Your bowling average is " Result Say "Your high game was " HighGame Say "Your low game was " LowGame Exit
	<pre>GA: Procedure Expose HighGame LowGame Arg Game1 Game2 Game3 Game4 Game5 Total = Game1 + Game2 + Game3 + Game4 + Game5 BowlAverage = Total / 5 HighGame = 0 If HighGame < Game1 then HighGame = Game1 If HighGame < Game2 then HighGame = Game2 If HighGame < Game3 then HighGame = Game3 If HighGame < Game4 then HighGame = Game4 If HighGame < Game5 then HighGame = Game5 LowGame = 300 If LowGame > Game1 then LowGame = Game1 If LowGame > Game2 then LowGame = Game3 If LowGame > Game3 then LowGame = Game4 If LowGame > Game5 then LowGame = Game5 Return BowlAverage In the above example, the first line is a Call to procedure "GA". It passes</pre>

five bowling scores.

The first thing that procedure "GA" does, is make the variables *HighGame* and *LowGame* available to the caller, by *Exposing* them. Note that if the entire *Procedure* statement was removed, all of the variables would be available. In larger programs, that could be a problem.

External

Purpose: Extract the number of terminal buffer or command stack elements that have been logically typed ahead by the terminal user.

See **PARSE EXTERNAL** for documentation on this subject.

Find

Purpose:	Return the position of a word/words in a sentence	
Type:	Rexx Function	
Syntax:	<i>Result</i> = FIND(<i>sentence,words</i>) where <i>result</i> is the word number where <i>words</i> appears in <i>sentence</i> . <i>Result</i> is 0 if <i>words</i> does not appear (as actual words) in <i>sentence</i> . (By definition, "word" is a character string enclosed by delimiters.)	
Examples: Position = FIND('Fourscore and seven years ago','years') will result in 4. years is the fourth word in the sentence.		
Position = FIND('Fourscoreandsevenyearsago','years') will result in 0. <i>years</i> does not appear as a word in the sentence. (The sentence contains only one word.)		
Say	FIND('Fourscore and seven years ago', 'and seven') will result in 2.	

Form

Purpose:	Returns the current setting of "Numeric Form".
Type:	Rexx Function
Syntax:	<i>CurrSetting</i> = Form() where CurrSetting will contain either "SCIENTIFIC" or "ENGINEERING"
	See also Numeric Form for documentation on this function.

Format

Purpose:	To print a number
Type:	Rexx Function
Syntax:	<i>Result</i> = Format(<i>number</i> , <i>left-of-decimal</i> , <i>right-of-decimal</i>) where <i>Result</i> is the formatted representation of number. <i>left-of-decimal</i> denotes how many digits to display on the left side of the decimal point, padded with blanks. <i>right-of-decimal</i> denotes how many decimal digits to display on the right side of the decimal point, zero-filled.
Usage:	This function is used to display numbers so they line up with others being displayed, or to display a number in a certain way.
Example:	<pre>/* Test1 - Example Rexx Program - Rexx EXEC */ Say "How much money did you have yesterday?" Pull YAmount Say "How much money do you have now?" Pull NAmount Diff = NAmount - YAmount If Diff > 0 then DiffWord = "Gained" else Diffword = "*Lost*" Diff = ABS(Diff) Say "Yesterday, you had \$" Format(YAmount,4,2) Say " Now, you have \$" Format(NAmount,4,2) Say "You "DiffWord" \$" Format(Diff,4,2) In the above example, when the Rexx exc asked: How much money did you have yesterday? And you answered: 2 And then the Rexx exce asked: How much money do you have now? And then you answered: 1.5 The Rexx exce would display: Yesterday, you had \$ 2.00 Now, you have \$ 11.50 You *Lost* \$ 9.50 Notice how the amounts line up. Without the formatting provided by the Format function, Rexx would display the following: Yesterday, you had \$2 Now, you have \$11.5 You Gained \$9.5</pre>

Fuzz

Purpose:	Returns the current setting of "Numeric Fuzz".
----------	------------------------------------------------

- Type: Rexx Function
- Usage: This is an inquiry as to this setting: how many low-order digits Rexx should ignore in comparisons.

See Numeric Fuzz for documentation on this function.

	••
Purpose:	Test for certain conditions (via program expressions), allowing action to be taken based on the results of the test.
Type:	Rexx Instruction
Syntax:	IF expression THEN instructionIf expression THEN DO one or more instructionsELSE instructionEND ELSE DO one or more instructionsEND ELSE DO One or more instructions
Expression:	Any valid program expression. If the statement is TRUE, the expression evaluates to a one. Conversely, if the expression is false, the expression evaluates to a zero. Rexx uses that value to determine whether it should execute the "THEN" instructions, or the "ELSE" instructions. The operators that can be used in an expression follow: > is greater than < is less than $/= \downarrow = <>$ is not equal = equal: numerically equivalent; equivalent when padded with blanks == strictly equal: exactly the same
Examples:	The following statements areTRUEFALSE $1 < 2$ $1 > 2$ $2 > 1$ $2 < 1$ $3 <> 4$ $4 <> 4$ "5b" = "5""5b" = = "5".02 = 0.02.02 = 0.02
Comparing strings:	Do NOT use "If >" to compare strings. Before a compare is done, high- order blanks are removed. Therefore, the following statement If " C4" < "BB3" will result in <i>false</i> .

You can use the *Compare* function to compare strings, but only for equality or inequality. To compare the value of strings, convert each character with *C2D* first, as follows:

```
Do N = 1 to length(OldKey)
If C2D(substr(OldKey,N,1)) < C2D(substr(NewKey,N,1)) then
Leave
If C2D(substr(OldKey,N,1)) > C2D(substr(NewKey,N,1)) then
Do
Say "The input file is out of sequence!"
Exit
End
End
```

If, Compound

Purpose:	To allow more than one expression in an "IF" statement.
Type:	Rexx Instruction
Syntax:	If <i>expression</i> bo <i>expression</i> bo <i>expression</i> Where: expression is as defined above bo is a Boolean operator.
Boolean operator:	 & All expressions are true At least one expression is true. (You must use the "OR" bar; you cannot use the word "OR" && Only one of two expressions is true, and not both
Examples:	<pre>If month = "DECEMBER" month = "JANUARY" , month = "FEBRUARY" then season = "WINTER" CandidateA = "Incumbent" CandidateB = "Incumbent" If CandidateA = "Incumbent" && , CandidateB = "Incumbent" then Say "Input is okay" Else Say "Dummy! They can't both be incumbents!" The previous excerpt of code will call you a dummy, because you told the </pre>

program that both candidates were incumbents.

If-Then-Do

Purpose:	Execute one or more instructions one time based on some condition.
Type:	Rexx Instruction
Syntax:	IF <i>expression</i> THEN DO END where <i>expression</i> is any valid Rexx expression.
Example:	<pre>If A = B then do (one or more instructions) End In this example, one or more instructions is executed only if A = B.</pre>

Index

Purpose:	Return the position of a character string in another
Type:	Rexx Function
Syntax:	<i>Result</i> = INDEX(<i>object</i> , <i>source</i>) where <i>result</i> is the position number where <i>source</i> appears in <i>object</i> . <i>Result</i> is 0 if <i>source</i> does not appear in <i>object</i> .
Note:	Index differs from Pos in that <i>object</i> and <i>source</i> are in opposite sequence in the command.
Examples:	
Linampiesi	Say Index('Fourscore and seven years ago','and seven') will return "11".
	Say Index('Fourscoreandsevenyearsago','andseven') will return "10".

Insert

Purpose: Copy a string into another string.

Type: Rexx Function

Syntax:Result-string = INSERT(new-string,old-string,where)
where result-string is the string that will contain the old-string with the
new-string inserted into it. new-string will be inserted into old-string after
the where position.
If where is greater than the length of old-string, then old-string wll be
padded with enough blanks to accomodate the insertion operation.

Examples:

Say Insert("Apple","Worm",2)
Will result in
WoApplerm
Say Insert("Apple","Worm",7)

Will result in Worm Apple (There are three spaces between "Worm" and "Apple").

Interpret

Purpose:	To make Rexx process an expression as an instruction; that is, execute instructions that have been built dynamically.
Type:	Rexx Instruction
Syntax:	INTERPRET expression1 expression2
Usage:	This is one of those highly esoteric Rexx functions. I have never had a need for this instruction (which is not to say a person never will).
Example:	<pre>1 Instr = "Say" 2 Var = "Hello World" 3 Instr Var 4 Interpret Instr Var Line 1 is simply setting the variable <i>Instr</i> to the character string "Say". Line 2 is simply setting the variable <i>var</i> to the character string "Hello World". Line 3 is being passed to TSO by Rexx, and the result is as follows: COMMAND SAY NOT FOUND 4 *-* Instr Var +++ RC(-3) +++ Line 4 tells Rexx not to pass these commands on to TSO, as it did with line 3, but to execute them instead. The result is: HELLO WORLD</pre>

Iterate

Purpose:	Pass through the remainder of the instructions in a "DO" loop without executing them.
Type:	Rexx Intruction
Syntax:	IF expression THEN ITERATE where expression is any valid Rexx expression.
Usage:	This is used to "skip" the remainder of a Do group.
Example:	<pre>/* Test1 - Example Rexx Program - Rexx EXEC */ Say "Please tell me your name" Pull YourName Do I = 1 to length(Yourname)</pre>

See the documentation on **Do** for more detailed information.

Justify

Purpose:	Justify a string to both margins.
Type:	Rexx Function
Syntax:	<i>NewString</i> = JUSTIFY(<i>string</i> , <i>length</i>) where <i>NewString</i> is the newly-created justified string; <i>string</i> is the character string being justified, and <i>length</i> is the length of <i>NewString</i> .
Usage:	A new string is created by justifying the old string to both margins, and adding blanks between words.
	If the specified length is less than the string, then the new string will be truncated on the right. Note that this should be viewed only as a side- effect, and not used purposely. Use the LEFT function instead when this is the desired effect.
	If there is only one word in the string being justified, it will be justified on the left.
Examples: The following excerpt from a Rexx exec: NewString = JUSTIFY('Hello, world! I am terrific!',30) Say NewString will result in NewString containing the following: Hello, world! I am terrific! within a 30-character field.	
NewSt Say N will re Hello	bllowing excerpt from a Rexx exec: tring = JUSTIFY('Hello, world! I am terrific!',10) WewString esult in NewString containing the following: b, wor a that only 10 positions were least

Notice that only 10 positions were kept.

Labels

Purpose:	To provide a target for the "Signal" instruction.
Syntax:	A label is immediately followed by a colon, with no intervening spaces.
Example:	Endit: Exit In the above example, "EndIt" is a label.

LastPos

Purpose:	Return the position of the last occurrence of one string within another.	
Type:	Rexx Function	
Syntax:	Position = LASTPOS(find-string,target-string) Where position is the position number of the last occurrence of find-string within target-string.	
Examples:	The following Rexx exec: XMasGreeting = "We wish you a Merry Christmas" Jingle = XMasGreeting XmasGreeting , XMasGreeting	
	Jingle = Jingle "And a Happy New Year!" Position = LASTPOS("Christmas",Jingle)	
	Say Position	
	will display "79". <i>XMasGreeting</i> appears 3 times in <i>Jingle</i> (and is 29 chracters long). The last occurrence of the word "Christmas" appears in the 79th position of <i>Jingle</i> .	

Leave

Purpose:	Prematurely exit from a "DO" loop.	
Type:	Rexx Instruction	
Syntax:	(None)	
Usage:	"Do loops" can be written in a number of different ways. The example below illustrates just one of those ways. In this particular example, the only graceful way of exiting is by use of the <i>Leave</i> instruction.	
Example:	<pre>/* Test1 - Example Rexx Program - Rexx EXEC */ Do Forever Say "Tell me your name, or enter 0 to quit" Pull Answer If Answer = "0" then Leave Say "You told me that your name was" Answer" End The above Rexx exec will echo back whatever you type in, until you enter a zero.</pre>	

Left

Purpose:	Return the left "n" positions of a string.
Туре:	Rexx Function
Syntax:	<i>NewString</i> = LEFT(<i>oldstring</i> , <i>quantity</i>) Where <i>NewString</i> is the leftmost <i>quantity</i> th positions of <i>oldstring</i>
Example:	In the following code, First8 = LEFT("ABCDEFGHIJKLMN",8) First8 will contain "ABCDEFGH"
See Also:	Right

Length

Purpose:	Return the length of a literal, string, or string variable
Type:	Rexx Function
Syntax:	Answer = LENGTH(variable)
Usage:	This is a Rexx built-in function that will return the length of a literal, string, or string variable.
Example:	Answer = length("Merry Christmas and Happy New Year") Say Answer Would display 34

LineSize

Purpose:	This is a Rexx built-in function that will return the terminal line width minus 1.
Type:	Rexx Function
Syntax:	<i>Result</i> = LineSize()
Usage:	This is an inquiry-only function, and will usually return "79".

ListDSI

Purpose:	Retrieve information about a TSO dataset.
Type:	TSO external function
Syntax:	LISTDSI(<i>datasetname directory</i>) or LISTDSI(<i>filename type directory</i>)
	 <i>datasetname</i>- the name of the data set about which you want information. <i>directory</i>- an option that indicates whether or not you want PDS directory information returned. DIRECTORY - return directory information. Note that this option must be specified if you want the PDS-specific variables below to contain the desired information (SYSADirBlk, for example). NODIRECTORY - Do not return directory information. This is the default. <i>filename</i> is the DD name if you pre-allocated the file
	<i>type</i> Specify 'FILE' if the first operand is a DDName instead of a datasetname
Usage:	This function will retrieve information about a dataset, and put it into variables.
	The function is said to succeed if it can access the desired dataset information, and fail if it cannot. The function in reality does not fail, however, because if the dataset cannot be allocated, LISTDSI sets three variables that say why.
	If the function succeeds, the return code is set to zero, and certain variables are set: SYSADirBlk For a PDS, this value will contain the number of directory blocks allocated. For a PDSE or sequential dataset, this value will be blank.
	SYSALLOCTotal space allocationSYSBLKSizeBlock size of the datasetSYSBLKSTrkBlocks per track for the unit that this file is onSYSCreateDate the dataset was initially created; julian date format: yyyy/ddd
	SYSDSNameFully-qualified datasetnameSYSDSorgDSORG of the dataset

SYSExDate	Expiration date of dataset. 0, if there is none.
SYSExtents	Number of extents used
SYSKEYLEN	Key length. 0 for non-keyed datasets
SYSLRECL	Logical record length
SYSMembers	Number of members in the PDS. This value
	is blank for PDSE's.
SYSPassword	The password assigned to the dataset, or "NONE"
SYSPrimary	Primary space allocation quantity
SYSRACFA	Level of RACF protection. Possible values
SISKACIA	are "NONE", "GENERIC", and
	"DISCRETE"
SYSRECFM	Record format of dataset
SYSRefDate	Date the dataset was last referenced; julian
	date format: yyyy/ddd
SYSSeconds	Secondary space allocation
SYSTrksCyl	The number of tracks per cylinder on the
	volume on which this dataset resides
	SYSUDirBlk. For a PDS, this value will contain the
	number of directory blocks used
SYSUnit	Generic unit of the volume, such as "3390" SYSUnits
	Units of allocation: "TRACK", "BLOCK",
	"CYLINDER", etc
SYSUpdated	Whether the dataset was ever updated: "YES" or "NO"
SYSUSED	Current space utilization: quantity of
	"SYSUnits" above. "N/A" for PDSE's
SYSVolume	The volume serial number on which this
	dataset resides
If the LISTDS	I function fails the raturn code is set to 16 and cortain

If the LISTDSI function fails, the return code is set to 16, and certain othervariables are set:SYSMSGLVL1SYSMSGLVL1Primary, or generic error messageSYSMSGLVL2Specific error message

SYSReason An error number

```
Examples:
            Consider the following Rexx Exec:
            /* Test1 - Example Rexx Program - Rexx EXEC */
            RC = listdsi(junk.data)
            If RC = 0 then do
                  Say "Allocation was successful."
                  Say "SYSADirBlk="SYSADirBlk
                  Say "SYSALLOC="SYSALLOC
                  Sav "SYSBLKSIZE="SYSBLKSIZE
                  Say "SYSCreate="SYSCreate
                  Say "SYSDSorg="SYSDSOrg
                  Say "SYSDSName="SYSDSName
                  Say "SYSExtents="SYSExtents
                  Say "SYSExDate="SySExDate
                  Say "SYSKEYLEN="SYSKEYLEN
                  Say "SYSLRECL="SYSLRECL
                  Say "SYSMembers="SYSMembers
                  Say "SYSPassword="SYSPassword
                  Say "SYSPrimary="SYSPrimary
                  Say "SYSRefDate="SYSRefDate
                  Say "SYSRACFA="SYSRACFA
                  Say "SYSRECFM="SYSRECFM
                  Say "SYSSeconds="SYSSeconds
                  Say "SYSTrksCyl="SYSTrksCyl
                  Say "SYSUnit="SYSUnit
                  Say "SYSUnits="SYSUnits
                  Say "SYSUpdated="SYSUpdated
                  Say "SYSUSED="SYSUSED
                  Say "SYSVolume="SYSVolume
            End
            Else do
                  Say "Return code = " RC
                  Say "SYSReason="SYSReason
                  Say "SYSMSGLVL1="SYSMsgLvl1
                  Say "SYSMSGLVL2="SYSMsgLvl2
            End
```

Using the above exec, I performed a LISTDSI on an existing PDS, and the Rexx exec reported as follows:

```
Allocation was successful.
SYSADirBlk=
SYSALLOC=15
SYSBLKSIZE=32720
SYSCreate=1997/104
SYSDSorg=P0
SYSDSName=DGRUND.WORK.DATA
SYSExtents=1
SYSExDate=0
SYSKEYLEN=0
SYSLRECL=80
SYSMembers=
SYSPassword=NONE
SYSPrimary=15
SYSRefDate=1997/107
SYSRACFA=GENERIC
SYSRECFM=FB
SYSSeconds=1
SYSTrksCyl=15
SYSUnit=3390
```

SYSUnits=TRACK SYSUpdated=YES SYSUSED=N/A SYSVolume=PCF011

Using the same exec, I performed a LISTDSI on an non-existent PDS, and the Rexx exec reported as follows: Return code = 16 SYSReason=0005

SYSMSGLVL1=IKJ58400I LISTDSI FAILED. SEE REASON CODE IN VARIABLE SYSREASON.

 $\mbox{sysmsglvl2=ikj58405i}$ data set not catalogued. The locate macro return code is 0008

Literals

Purpose:	Literals exist so variables can represent an unchanging value. Rexx supports literals of a number of different types.
Usage:	Typically, a literal is one that is enclosed by either a set of quotation marks or apostrophes. "HELLO WORLD" and 'HELLO WORLD' represent the same character string.
	Literals can be numeric, character, hexadecimal, and binary. "FOUR" is a character literal; "4" is a numeric literal.
	 The reason I say "typically", is because that is not always the case. (This is probably one of my biggest complaints about Rexx. I feel that if it was more stringent, it would be easier to figure out and explain.) A character literal doesn't <i>have to</i> be enclosed. If it isn't, it is changed to all upper case. A character literal that is not enclosed can be converted to a variable by using it on the left side in an assignment statement. (You will get a syntax error if you try to assign a literal that is enclosed).
	Consider this example. The following excerpt is from a Rexx Exec: Say "Hello, World" /* Character string */ Say Hello World /* Two literals */ World = "Dave" /* Make "World" a variable */ Say Hello World will yield the following results: Hello, World HELLO WORLD HELLO Dave
	A good rule of thumb to follow is always enclose literals. That way, if a character string appears in your output, you can bet it's an (uninitialized) unused variable.

Logical Operators

REXX supports the following logical (Boolean) comparison operators:

& AND - returns a 1 (true) if both comparisons are true, and a 0 (false) otherwise - performs a logical AND operation

| OR - returns a 1 (true) if at least one comparison of several is true, and a 0 (false) otherwise - performs a logical or operation

&& EXCLUSIVE OR - returns a 1 (true) if ONLY one of a group of comparisons is true, and a 0 (false) otherwise - performs a logical exclusive OR function

 \setminus NOT - returns the reverse logical value for an expression - returns false if expression resolves to true, and true if the rexpression resolves to false

Math

Rexx performs math whenever it can recognize arithmetic operators. The valid Rexx operators are as follows:

Operator	Function
+	Add
-	Subtract
*	Multiply
/	Divide
%	integer divide
//	remainder of division
**	Exponentiation
()	group items

Usage

The primary operations (+, -, *, /) are obvious, so not much further discussion is needed here.

%- Integer

Divide Any remainder is dropped

//- Remainder

```
of Division Yields the remainder in a division expression.
The following excerpt from a Rexx exec:
"EXECIO" 1 "DiskW SYSUT2"
OpCount = OpCount + 1
If OpCount // 1000 = 0 then
Say OpCount "records written so far..."
will print a message line for every 1000th record written. This, of course, is
```

useful in a long-running program.

**- Exponentation

() Operations within expressions to make them take precedence over normal precedence.

Max

Function:	Return the highest of a series of numbers.
Type:	Rexx Function
Syntax:	HighNum = MAX(num1, num2)
Usage:	A maximum of 20 numbers can be provided.
Example:	Say Max(1,3,5,17,9,6,4) will yield "17" (without the quotation marks)

Min

Purpose:	Return the lowest of a series of numbers.
Type:	Rexx Function
Syntax:	LowNum = MIN(num1, num2)
Usage:	A maximum of 20 numbers can be provided.
Example:	Say Min(8,3,5,17,9,6,4) will yield "3" (without the quotation marks)

Msg

Purpose:	Change or inquire as to the current TSO "MSG" setting.	
Type:	TSO external function	
Syntax:	Setting = MSG(<i>on/off</i>) where <i>setting</i> is the current setting, <i>before</i> it is changed by what is in the parentheses; <i>on/off</i> is either "ON", "OFF", or nothing.	
Usage:	The TSO "MSG" setting indicates whether TSO messages are printed during the execution of a Rexx exec or not. Specify the command with "ON" to turn message displays on, "OFF" to turn message displays off, and a null parameter (just the parentheses with nothing in them) to display the current setting.	
Example 1:	In the following example, 1 Say Msg() 2 MSetting = Msg(Off) 3 Say MSetting 4 Say Msg() 1 will display the current TSO message setting, either "ON" or "OFF" 2 will capture the current TSO MSG setting into the variable <i>MSetting</i> , and then set the setting to "OFF", regardless of what it was 3 will display the variable <i>MSetting</i> 4 will display the new current setting, which will be "OFF"	
Example 2:	<pre>In the following example, 1 Say Msg() 2 Say "About to allocate the first time" 3 "Allocate FI(dummy) DA(junk2.data) shr" 4 Junk = Msg(Off) 5 Say "About to allocate the second time" 6 "Allocate FI(dummy) DA(junk2.data) shr" 1 will display the current TSO message setting, either "ON" or "OFF" 2 tells the user that we are about to issue a TSO command 3 allocates the file, if possible 4 turns the MSG setting off 5 tells the user again that we are about to issue a TSO command 6 allocates the file again, if possible The dataset junk2.data does not exist, so each attempt at allocating it will fail. Line 3 above will issue a message because the TSO MSG setting is on. Line 6 above would have issued a TSO message, but the TSO MSG setting was off.</pre>	

NewStack

Purpose: Establish a new TSO stack

Type: TSO command

Syntax: NewStack

Usage: To tell Rexx that from here on, all stack operations are to be conducted on a newly-established TSO stack, instead of the one that existed when the instruction started. The "old" stack is left alone and unharmed by further operation, until a DelStack is issued to discard this newly-established stack.

See also: DelStack

NOP

Purpose:	No operation	
Type:	Rexx instruction	
Syntax:	NOP	
Usage:	Allow you to use an instruction that performs no action in a place where an instruction (of any kind) is required.	
Example:	The following example is coded this way to avoid complicated negative logic. If A = 1 A = 2 then Nop /* do nothing */ Else Say "answer was incorrect"	

Numeric

Purpose:	Set certain rules for Rexx's handling of numbers. It controls the waya Rexx
	exec carries out arithmetic operations.

Type: Rexx instruction

Syntax:Numeric functionWhere function is either Digits, Form, or Fuzz.

Digits controls the precision to which arithmetic operations are evaluated.

- Form directs which form of exponential notation Rexx uses of the result of arithmetic operations
- Fuzz controls how many digits, at full precision, are ignored during a numeric comparison operation.

In many cases, these three functions work together to produce the desired results.

Numeric Digits

- Purpose: Controls the precision to which arithmetic operations are evaluated.
- Syntax: Numeric Digits *NoOfDigits* NoOfDigits - Defaults to 9, and must be larger than the current NUMERIC FUZZ setting. There is no practical limit to the value for DIGITS, but keep in mind that higher values result in added processing time.
- Example: The following Rexx exec snippet: Numeric Digits 5 ; Say 1234.56 * 1 Numeric Digits 4 ; Say 1234.56 * 1 Numeric Digits 3 ; Say 1234.56 * 1 Numeric Digits 2 ; Say 1234.56 * 1 Numeric Digits 1 ; Say 1234.56 * 1

Will produce: 1234.6 1235 1.23E+3 1.2E+3 1E+3

Numeric Form

Purpose:	Directs which form of exponential notation Rexx uses for the result of arithmetic operations
Syntax:	Numeric Form <i>mode</i> Where <i>mode</i> is either SCIENTIFIC or ENGINEERING SCIENTIFIC notation adjusts the power of ten so there is a single non- zero digit to the left of the decimal point. ENGINEERING notation causes the power of ten to be expressed as a multiple of 3.
Example:	The following Rexx exec snippet: Numeric Digits 2 Numeric Form Scientific Say 123.45 * 1 Numeric Form Engineering Say 123.45 * 1 Will produce: 1.2E+2 120

Numeric Fuzz

Purpose:	Controls how many (low-order) digits, at full precision, are ignored during a numeric comparison operation. The <i>exact</i> way this function works is actually slightly complicated.	
Syntax:	Numeric Fuzz <i>ToIgnore</i> <i>ToIgnore</i> - Defaults to 0. It must be smaller than the current setting of NUMERIC DIGITS.	
Usage:	During the numeric comparison, the numbers are subtracted under a precision of DIGITS minus FUZZ digits, and the difference is then compared to 0.	
Example 1:	The following Rexx exec snippet: Value1 = 133456 Value2 = 123457	
	Numeric Digits 6 Numeric Fuzz 5 If Value1 = Value2 then Say "They are equal" Else Say "They are NOT equal"	
	Will produce: They are equal Digits (6) minus Fuzz (5) equals 1. That is the number of digits from the left that are compared. Since the first digit in each of Value1 and Value2 are identical, this comparison is true.	
Example 2:	The following Rexx exec snippet: Value1 = 133456 Value2 = 123457	
	Numeric Digits 6 Numeric Fuzz 5 If Value1 = Value2 then Say "They are equal" Else Say "They are NOT equal"	
	Numeric Fuzz 4 If Value1 = Value2 then Say "They are equal" Else Say "They are NOT equal"	
	Will produce: They are equal	

Digits (6) minus Fuzz (4) equals 2. That is the number of digits from the left that are compared. The first two digits of Value1 (13) are compared to the first two digits of Value2 (12). This comparison is obviously false.

Operators

Arithmetic Operators- See the subject entitled "Math" Comparison Operators- See the subject entitled "Compare" Logical Operators- See the subject entitled "Logical Operators" Concatenation Operators- See the subject entitled "Concatenation"

REXX Operator Precedence

The following list shows order of precedence for ALL REXX operators:

1) Expressions in parenthesis are evaluated first

- 2) prefix operators ==> -, + \setminus
- 3) exponentiation ==> **
- 4) Multiplication and division in this order ==> *,/, %,//
- 5) Addition and Subtraction ==> + and -
- 6) concatenation $==> \parallel$ or blank
- 7) comparison operators ==> ==,=,\==,\=,>,<,><,>=,<=,\<,>>
- 8) logical AND => &
- 9) logical OR and EXCLUSIVE OR ==> |, &&

OutTrap

Purpose:	To turn on or off the capturing of TSO output.	
Type:	TSO external function	
Syntax:	<i>ReturnCode</i> = OUTTRAP(<i>stem.,max</i>) <i>ReturnCode</i> = OUTTRAP('ON'/OFF') where <i>stem.</i> is the name of the array into which the TSO output will be built, and <i>max</i> is the maximum number of records that will be written. Note that <i>stem</i> <u>must</u> end in a period. <i>ReturnCode</i> will be 0 if the function succeeds.	
Usage:	OUTTRAP("ON"): Turn on capturing of TSO messages and output, simply "swallow" it. Nothing wil be displayed at the terminal. OUTTRAP("OFF"): Stop the capture of TSO messages and output, in which case they will start being displayed at the terminal again. OUTTRAP(<i>stem.,max</i>): Turn on capturing of TSO messages and output, and write it all to an array named <i>stem. max</i> is the maximum number of records that will be written. Specify "*" to process all records, although that is the default.	
Example:	<pre>In the following example, we are trying to write all of the member names of a PDS to an array. As a byproduct of the TSO command that we are using, some unwanted information is written to the array as well. Dummy = OutTrap("output_line.","*") "LISTd work.data m" NumLines = OutPut_Line.0 Say NumLines "lines were created" Dummy = OutTrap("OFF") Do I = 0 to NumLines Say "Output_Line."I"="Output_Line.I End After execution of this exec, the array called Output_Line looks like this: Output_Line.0=8 Output_Line.1=DGRUND.WORK.DATA Output_Line.2=RECFM-LRECL-BLKSIZE-DSORG Output_Line.3= FB 80 32720 PO Output_Line.5= PCF011 Output_Line.6=MEMBERS Output_Line.6=-PROG01 Output_Line.8= PROG02 There are only two members in the PDS, but the array contains all of the other output from the ListDS command. It's really simply to process around it, though, like this: Da L = T the output the is: Da L = T the output the is: Data = T the output the outp</pre>	

Overlay

Purpose:	Move characters over (on top of) other characters.	
Type:	Rexx Function	
Syntax:	NewString = OVERLAY(source,object,position)	
Usage:	This function replaces the characters in object with the characters in source, starting at position. If object is less than position, it is padded with blanks.	
Example 1:	This is what happens when you use the command the wrong way: NewString = OVERLAY("ABCDEFGHIJK",'X',4) Say Newstring NewString will contain: X ABCDEFGHIJK	
Example 2:	<pre>The following example decides, based on the day of the week, whose turn it is to make the coffee. Say "Today is " Date(W) CoffeeMaker = "Undecided" /* default */ If Date(W) = "Monday" then CoffeeMaker = "Glenda" If Date(W) = "Tuesday" then CoffeeMaker = "Alice" If Date(W) = "Wednesday" then CoffeeMaker = "Thom" If Date(W) = "Thursday" then CoffeeMaker = , "Brucey" If Date(W) = "Friday" then CoffeeMaker = "Chuck" Message = "The person in charge of making coffee -> today is" Position = length(Message) + 2 Say OVERLAY(Coffeemaker,Message,Position)</pre>	

Parse

Purpose:	Take data from one of several origins, optionally break it up, and then drop it into variables.	
Type:	Rexx Instruction	
Syntax:	PARSE [UPPER] origin varname delimiter varname delimiter UPPER- Converts the data to upper case. This is the default. origin- Places where REXX can get the data from: ARG- Command line VAR- A variable PULL- The TSO stack SOURCE- TSO info on how the program was executed VALUE- Literal EXTERNAL- Terminal VERSION- Version of Rexx interpreter varname- One or more variables delimiter- Delimiters for parsing the origin data	
Note:	The words "Parse Upper" are optional. When Rexx sees any of these origins, it assumes "Parse Upper".	
Upper:	"Upper" is optional, but it is the default. To <i>not</i> take the default, simply specify "Parse" without the word "Upper".	
Action:	Rexx will move variables one at a time from the implied origin into the variables specified after the origin keyword.	
If there are more origin parameters than variables, Rexx will put all or remaining parameters into the last variable. The last variable can be a period, in which case extra origin parameters will simply be discarded don't recommend this, however. Letting these drop into a variable wo not hurt. You can always choose to ignore them, but the program will require no modification here if you later choose to look at these parameters.		
	If there are more variables than there are origin parameters, the variables are set to spaces.	
	Delimiters break the input up and cause it to be processed separately, under the guidelines specified above.	

ARG:	Take input from the command line. This is information that the user supplied to the exec when entering the command. See examples EX01 and EX02 below.	
VAR:	Take input from a variable. See example EX03 below.	
PULL:	Take input from the TSO stack. Use PULL to prompt the user for information. (Whatever the user types in is moved into the TSO stack.) See example EX04 below.	
SOURCE:	 Take input from information that the system (TSO) maintains about your REXX program. It returns nine values. They are: 1. Operating System. In this case, it would be TSO. 2. How the program (Rexx exec) was called. It will be either of COMMAND, SUBROUTINE, or FUNCTION. 3. Name of the EXEC 4. DDName of command library; either SYSEXEC or SYSPROC 5. Datasetname containing the EXEC. It will be '?' if the command was invoked implicitly. 6. The name that the command was invoked by. It will be "?" if the command was invoked implicitly. 7. The initial address environment; generally TSO, MVS, or ISPEXEC 8. Environment: TSO, MVS, or ISPF 9. Reserved. Will be '?' See example EX05 below. 	
VALUE:	Take input from a literal. This function can be used to parse things like the current time. See example EX06 below.	
EXTERNAL:	Take input from the terminal.	
varname:	One or more variable names	
Delimiters:	Delimiters to determine where origin data is divided. These delimiters can be literals, variables, or column numbers.	
Literal Delimiters:	Break input up at a specific character. See example EX03 below.	
Variable Delimiters:	Break input up at a specific variable	
Column numb Delimiters:	er Break input up under the control of column numbers.	

Examples: I used the origins that I did for the sake of clear explanation only. The following examples apply to all of the origins.

```
In the following Rexx program,
/* EX01 - REXX Example Program */
Parse Upper Arg Var1 Var2 Var3 Var4 Var5
Say Var1 ; Say Var2 ; Say Var3 ; Say Var4 ; Say Var5
If the command line read
      Ex01 a b c d e
Rexx would display
      Α
      В
      С
      D
      Е
If the command line read
      Test1 a b c d e f g h
Rexx would display
      Α
      В
      С
      D
      EFGH
If the command line read
      Testl a b
Rexx would display
      Α
      В
      (with three blank lines following)
If the command line read
      Test1 "My name is Dave"
Rexx would display
      "MY
      NAME
      IS
      DAVE "
      (blank line)
In the following Rexx program,
/* Ex02 - REXX Test Program */
Parse Arg Var1 Var2 Var3 Var4 Var5
Say Var1 ; Say Var2 ; Say Var3 ; Say Var4 ; Say Var5
If the command line read
      EX02 a b c d e
Rexx would display
      а
      b
```

С d e In the following Rexx program, /* EX03 - REXX Test Program */ Parse upper arg datasetname Parse var datasetname PDSName "(" MemName ")" junk Say "The command line parameter was " DatasetName " PDSName " MemName " junk Say "The PDSName is Say "The MemberName is Say "The junk variable is If the command line read EX03 user.session.jcl(copyfile) Rexx would display The command line parameter was USER.SESSION.JCL(COPYFILE) The PDSName is USER.SESSION.JCL The MemberName is COPYFILE In the following Rexx program, /* EX04 - REXX Example Program */ Newstack Say "Please tell me your first and last name" Pull FirstName LastName Say "You told me your first name was" FirstName Say "You told me your last name was" LastName DelStack If the command line read EX04 Rexx would display Please tell me your first and last name And if you replied George Washington Rexx would display You told me your first name was GEORGE You told me your last name was WASHINGTON In the following Rexx program, /* EX05 - REXX Example Program */ Parse Upper Source Stuff Say Stuff Rexx would display something like TSO COMMAND EX05 SYSEXEC ? ? TSO ISPF ? In the following Rexx program, /* EX06 - REXX Example Program */ Parse Value Time() with Hrs ':' Mins ':' Secs Say Hrs; Say Mins; Say Secs If the time of day was 10:28:07, Rexx would display 10 28

/* EX07 - REXX Example Program */
Parse Version Me
Say Me
would display something like the following:
REXX370 VERS 3.48 01 May 1992

07

Pos

Purpose:	This is a Rexx built-in function that will allow you to determine if a character is present in a string or variable, by returning its position in the string.
Туре:	Rexx Function
Syntax:	<i>Position</i> = POS(<i>source</i> , <i>object</i>) where <i>position</i> is the <i>position</i> of <i>source</i> within <i>object</i> . <i>Position</i> will be zero if <i>source</i> does not apear in <i>object</i> .
Note:	Index differs from Pos in that <i>object</i> and <i>source</i> are in opposite sequence in the command.
Example:	<pre>We will use the following Rexx exec for our examples: /* Test1 - Check for Coffeemakers - REXX exec */ Arg Person CoffeeMakers = "GLENDA ALICE THOM BRUCEY CHUCK DAVE " If Pos(Person,Coffeemakers) > 0 then say Person "is indeed one of our CoffeeMakers" Else say Person "does not drink coffee with us" The following command: Test1 Alice will yield the following message: ALICE is indeed one of our CoffeeMakers because POS contains 8 The following command: Test1 Randy will yield the following message: RANDY does not drink coffee with us because POS contains 0 The following command: Test1 Al will yield the following message: RANDY does not drink coffee with us because POS contains 0 The following command: Test1 Al will yield the following message: AL is indeed one of our CoffeeMakers This is an error, not in the Rexx exec, but in our usage of it. We are checking only for the existence of the character string and not whether that</pre>

This is an error, not in the Rexx exec, but in our usage of it. We are checking only for the existence of the character string, and not whether that charcter string is a whole word.

Procedure

Purpose: Establish that the current block of code is a Procedure, and thereby hide all local variables

Type: Rexx Instruction

Syntax: PROCEDURE

Usage: This statement is needed only when you wish to hide the variables that appear in the local block of code. You can then "unhide" some of them by using the **Expose** function.

See **Expose** for more information.

Prompt

Purpose:	Change the setting of, or inquire as to the current setting of the TSO "Prompt" setting.	
Type:	TSO external function	
Syntax:	Answer = PROMPT("ON" "OFF")	
Usage:	Rexx PROMPT functions only if the TSO PROFILE PROMPT setting is "ON")as opposed to "PROFILE NOPROMPT").	
	The "ON" parameter will cause Rexx to allow TSO commands to prompt for necessary information.	
	The "OFF" parameter will force TSO commands to bypass the normal step of stopping and asking for missing information.	
	In both of the above cases, the function will first return the current setting.	
	The empty parameter will simply return the current setting.	
Example:	<pre>The following exec is actually the same process run twice; once after turning the TSO Profile Prompt setting ON, and once turning it off. During each process, we will turn the Rexx Prompt setting on, issue the TSO "Delete" command, and then turn the Rexx Prompt setting off, and then issue the same TSO delete command. If you get confused, just remember that there is a difference bewteen the TSO Prompt command and the Rexx Prompt function. "Profile Prompt" Say "Here is the demo with the TSO prompt ON" Dummy = prompt("ON") Say "Rexx Prompt is " prompt() "Newstack" Delete "Delstack"</pre>	
	Say "Rexx Prompt is " prompt() "Newstack" Delete "Delstack"	
	"Profile NoPrompt" Say "Here is the demo with the TSO prompt OFF" Dummy = prompt("ON") Say "Rexx Prompt is " prompt() "Newstack" Delete	

```
"Delstack"
Dummy = prompt("OFF")
Say "Rexx Prompt is " prompt()
"Newstack"
Delete
"Delstack"
```

This exec will display: Here is the demo with the TSO prompt ON Rexx Prompt is ON ENTER ENTRY NAME -At which point, the command waits for a datasetname to be entered. I entered "A".

```
Continuing the display...
ERROR QUALIFYING GRUND.A
** DEFAULT SERVICE ROUTINE ERROR CODE 20, LOCATE
ERROR CODE 8
LASTCC=8
Rexx Prompt is OFF
MISSING ENTRY NAME+
LASTCC=12
MISSING ENTRYNAME TO BE DELETED, PASSWORD OPTIONAL
Here is the demo with the TSO prompt OFF
Rexx Prompt is ON
MISSING ENTRY NAME+
LASTCC=12
MISSING ENTRYNAME TO BE DELETED, PASSWORD OPTIONAL
Rexx Prompt is OFF
MISSING ENTRY NAME+
LASTCC=12
MISSING ENTRYNAME TO BE DELETED, PASSWORD OPTIONAL
```

In the above exec, I tried the following 4 scenarios:

TSO	REXX	Prompting
PROMPT	PROMPT	Occurred?
ON	ON	YES
ON	OFF	NO
OFF	ON	NO
OFF	OFF	NO

In each case where prompting did not occur, TSO went along its merry way, trying to delete a dataset whose name wasn't supplied. Naturally, it failed.

Pull

Purpose:	Get input from TSO	
Type:	Rexx Instruction	
Syntax:	Pull variable1 variable2	
Usage:	This command will first look at the TSO stack. If the TSO stack is empty, the command will prompt the user.	
Example:	 NewStack Push "Hello #1" Pull Answer1 Say "I just learned" Answer1 Pull Answer2 Say "I just learned" Answer2 In this example, Establishes a new stack Puts the phrase "Hello #1" onto the stack Gets (and removes) that phrase from the stack Displays I just learned HELLO #1 Prompts the user for more input, since the stack is now empty Displays whatever the user just typed in. 	

Push

Purpose:	Move data to the TSO stack.
Type:	Rexx Instruction
Syntax:	PUSH variable1 variable2
Usage:	Put things in the "input queue". This instruction works in LIFO format: last in, first out. It operates like a pile of plates in a diner. The plates put on top push the others down, and the first ones pulled off are the last ones put on. Queue does the same thing as Push, but in FIFO format.
Example 1:	<pre>1 NewStack 2 Say "I have "queued()" lines on the stack" 3 Push "A" "B" "C" 4 Say "I have "queued()" lines on the stack" 5 Pull var1 6 Say "I pulled "Var1" off of the stack" 7 Say "I have "queued()" lines on the stack" Line 1 established a brand new TSO stack to play with. Line 2 tells us how many lines are on the stack. This should be "zero", since we just started a new stack. Line 3 pushed three variables (one line) onto the stack. Line 4 again tells us how many lines are on the stack, so now the stack again contains zero lines. Line 6 tells us the variables that the exec pulled off the stack Line 7 again tells us how many lines are on the stack. This should be "zero".</pre>
Example 2:	Newstack Say "I have "queued()" lines on the stack" Push "A" "B" "C" Push "D" "E" "F" Say "I have "queued()" lines on the stack" Pull varl Say "I have "queued()" lines on the stack" Say "I pulled "Varl" off of the stack" Pull varl Say "I pulled "Varl" off of the stack" Say "I pulled "Varl" off of the stack" In this example, "A B C" is pushed onto the stack. Then "D E F" are pushed onto the stack. Since <i>Push</i> is a LIFO instruction, the program will first pull "D E F" off the stack, then "A B C".

QStack

Purpose:	Determine the number of data stacks currently in existence
Type:	TSO Command
Syntax:	QStack
Usage:	To see if the exec (or subroutines) had created any data stacks
See also:	NewStack, DelStack
Example:	The following Rexx exec snippet: "QStack" /* Returns a 1 in RC */ saverc = RC /* Save the number of stacks */ Say "The number of data stacks is " saverc "NewStack" /* Create a new data stack */ "NewStack" /* Create a new data stack */ "QStack" /* Returns a 3 in RC */ saverc = RC /* Save the number of stacks */ Say "The number of data stacks is " saverc Will display: The number of data stacks is 1 The number of data stacks is 3

Queue

Purpose:	Move data to the TSO stack.
Type:	Rexx Instruction
Syntax:	Queue variable1 variable2
Usage:	Put things in the "input queue". This instruction works in FIFO format: First in, first out. Push does the same thing as Queue, but in LIFO format.
Example 1:	<pre>1 NewStack 2 Say "I have "queued()" lines on the stack" 3 Queue "A" "B" "C" 4 Say "I have "queued()" lines on the stack" 5 Pull var1 6 Say "I pulled "Var1" off of the stack" 7 Say "I have "queued()" lines on the stack" Line 1 established a brand new TSO stack to play with. Line 2 tells us how many lines are on the stack. This should be "zero", since we just started a new stack. Line 3 pushed three variables (one line) onto the stack. Line 4 again tells us how many lines are on the stack, so now the stack again contains zero lines. Line 6 tells us the variables that the exec pulled off the stack Line 7 again tells us how many lines are on the stack. This should be "zero".</pre>

Queued

Purpose: This is a Rexx built-in function that will return the number of lines that are currently available in the TSO stack.

Type: Rexx Function

Syntax: NumOfLines = Queued()

Example:

If Queued() > 0 then DelStack In the above example, if there are any lines on the TSO stack, we will delete them.

Quotation Marks/Apostrophes

Purpose:	To enclose a literal (character string).
Syntax:	"" or ''
Usage:	Literals are enclosed by a matched set of either apostrophes or quotation marks. They can be used interchangeably, but must be used in matched pairs.
	A character string containing apostrophes can be enclosed by quotation marks, or vice-versa.
	The Rexx instruction:Yields:Say "Hello, it's me!"Hello, it's me!Say 'Hello, it"s me!'Hello, it"s me!
	Say 'Hello, it"s me!' Hello, it"s me!
	(Although the punctuation is incorrect)
	A character string containing apostrophes can be enclosed by apostrophes only if each of the contained apostrophes is represented by two. The Rexx instruction: Yields: Say 'Hello, it's me!' Error: unmatched quote Say 'Hello, it''s me!' Hello, it's me! The first example (enclosing apostrophes in quotation marks) is cleaner, and is the recommended method.
	Enclosing an expression causes Rexx to bypass the command, and pass it right through to the environment; in our case, TSO. Example: "Say 'Hello, World' " Would display COMMAND SAY NOT FOUND 8 *-* "Say 'Hello' " +++ RC(-3) +++

Random

Purpose:	Return a random number
Type:	Rexx Function
Syntax:	<i>Pick</i> = RANDOM(<i>min,max,seed</i>) where <i>pick</i> is the number selected; <i>min</i> and <i>max</i> is the range of numbers, inclusive, from which the function can pick; and <i>seed</i> is the random number seed; it is optional.
Usage:	This function will pick a number that is commonly referred to as pseudo- random. Specifying the same seed will produce the same random number. Random
Example:	This is an example of an Exec that thinks it camn guess what the current temperature is. MoNum = substr(Date(U),1,2) If Monum = 1 then Do; Low = 0; High = 55; end If Monum = 2 then Do; Low = 0; High = 60; end If Monum = 3 then Do; Low = 15; High = 65; end If Monum = 4 then Do; Low = 35; High = 80; end If Monum = 5 then Do; Low = 45; High = 85; end If Monum = 6 then Do; Low = 50; High = 90; end If Monum = 7 then Do; Low = 55; High = 95; end If Monum = 8 then Do; Low = 55; High = 95; end If Monum = 9 then Do; Low = 50; High = 90; end If Monum = 10 then Do; Low = 30; High = 85; end If Monum = 12 then Do; Low = 0; High = 60; end Temp = Random(Low,High) Say "The temperature right now is " Temp

RC

Purpose:	Special variable set by TSO commands
Usage:	This variable can be used to test the success/failure of a TSO command.
Example 1:	<pre>1 Say "This is a typical Rexx instruction" 2 Say "Return Code = "RC 3 Junk 4 Say "Return Code = "RC 5 Say "Hello, World" 6 Say "Return Code = "RC 7 Say A = B + C 8 Say "Return Code = "RC 2 Say "Return Code = "RC Line 1 will simply display a message. Line 2 wil display Return Code = RC. Line 1 was a Rexx instruction, and did not set RC. Since RC was never set (in this exec), it is stil undefined. Line 3 is not a Rexx instruction, so it is passed on to TSO, and the following displays: COMMAND JUNK NOT FOUND 3 *-* Junk +++ RC(-3) +++ Line 4 displays: Return Code = -3 Lines 5-6 display: Hello, World Return Code = -3 Return code was set to -3 before, and is unchanged because these are both valid Rexx instructions. Line 7 displays: 7 +++ Say A = B + C Error running T1, line 7: Bad arithmetic conversion The Rexx exec stops here, so line 8 never executes.</pre>

Result

Purpose:	Special TSO variable set by the Return instruction
Usage:	This variable is set by the Return instruction after a subroutine is called. If the subroutine returns an expression, Result will contain that expression. If not, Result is dropped (becomes uninitialized).
Example:	The following exec: Call Proc1 Say "Result is " Result Call Proc2 Say "Result is " Result Exit Proc1: Return "abc" Proc2: Return Will display: Result is abc Result is RESULT

Return

Purpose:	Go back to a caller
Туре:	Rexx Instruction
Syntax:	RETURN variable
Usage:	Use this command to return to a calling program, and optionally pass a variable. The variable that is passed back will be moved into the "RESULT" variable for use by the caller.
Example 1:	Call Multiply 2 3 Say "The answer is "Result Exit Multiply: Arg Factor1 factor2 Product = Factor1 * Factor2 Return Product The above example illustrates the use of the <i>Return</i> function and the <i>Result</i> wrights You could have exacting of the <i>Return</i> function and the <i>Result</i>
	variable. You could have specified <i>Product</i> instead of <i>Result</i> , but that

variable. You could have specified *Product* instead of *Result*, but that would have violated good programming techniques, and depending how the subroutine is coded, may not give you the desired results. The illustrated way always will.

Reverse

Purpose:	Reverses the order of the characters of a string.
Type:	Rexx Function
Syntax:	Result = REVERSE(string)
Usage:	Use this function to turn a string around.
Example 1:	The following Rexx EXEC: Message = "Happy birthday to you" NewMsg = REVERSE(Message) Say "The original message was " Message Say "The new message is " NewMsg Will display: The original message was Happy birthday to you The new message is uoy ot yadhtrib yppaH The following Rexx EXEC: Message = "Able was I ere I saw Elba" NewMsg = REVERSE(Message) Say "The original message was " Message Say "The new message is " NewMsg Will display: The original message was Able was I ere I saw Elba The new message is able was I ere I saw Elba I used a palindrome here to illustrate a point: the case of the letters will remain the same as they were.

Right

Purpose:	Return the right "n" positions of a string.
Type:	Rexx Function
Syntax:	<i>NewString</i> = RIGHT(<i>oldstring</i> , <i>quantity</i>) Where <i>NewString</i> is the rightmost <i>quantity</i> th positions of <i>oldstring</i>
Example:	In the following code, First8 = RIGHT("ABCDEFGHIJKLMN",8) First8 will contain "GHIJKLMN"
See Also:	Left

Say

Purpose:	Display strings, literals, and numeric values
Type:	Rexx Instruction
Syntax:	Say anything
Usage:	This command is probably the most commonly-used Rexx command. It is used to display information to the user at the terminal. You can mix literals and variables into the object that you are displaying.
Example: Say "Hello, World. My name is Computer. What is your name?" Pull YourName Say "So, you say your name is" YourName"." Say "How old are you, "YourName"?" Pull YourAge Say "Hmmmm" YourAge", huh? That's pretty good. I used to be", YourAge "once, too!" Say "Goodbye, "YourName", and have another wonderful "YourAge" years!"	
The above example first asks you for your name, and then your age.	

Select

Purpose:	Rexx's implementation of the structured programming CASE construct.
Type:	Rexx Instruction
Syntax:	SELECT WHEN expression THEN instruction WHEN expression THEN instruction WHEN expression THEN instruction WHEN expression THEN instruction OTHERWISE instruction
Example:	<pre>SELECT WHEN WeekDay = 1 THEN DOWWord = "Sunday" WHEN WeekDay = 2 THEN DOWWord = "Monday" /* The rest of the days of the week */ OTHERWISE DOWWord = "Invalid" END</pre>

Semi-Colon

Purpose:	To stack instructions on a line
Syntax:	instruction; instruction;
Usage:	Use this command to place more than one instruction on a line, especially when they are "short" instructions. Stacking instructions on a line can compact the body of a routine so you can see more of it at one time. Sometimes, this can be a help instead of a deterrent.
Example 1:	<pre>Temperature = Random(1,100) If temperature < 20 then do Weather = "Brutal"; Like = "heck no!" End If temperature > 19 & temperature < 32 then do Weather = "Cold"; Like = "no" End If temperature > 31 & temperature < 50 then do Weather = "Nippy"; Like = "not really" End If temperature > 49 & temperature < 71 then do Weather = "so-so"; Like = "so-so" End If temperature > 70 & temperature < 82 then do Weather = "warm"; Like = "nice" End If temperature > 81 then do Weather = "hot"; Like = "yes!" End Say "The temperature now is "temperature, " and the weather is "Weather"." Say "Do I like it? "Like In the above example, there are two short instructions in every If-then-do group. They each take two lines.</pre>

Example 2:

```
Temperature = Random(1, 100)
If temperature < 20 then do
   Weather = "Brutal"; Like = "heck no!"
End
If temperature > 19 & temperature < 32 then do
    Weather = "Cold"; Like = "no"
End
If temperature > 31 & temperature < 50 then do
    Weather = "Nippy"; Like = "not really"
End
If temperature > 49 & temperature < 71 then do
    Weather = "so-so"; Like = "so-so"
End
If temperature > 70 & temperature < 82 then do
    Weather = "warm"; Like = "nice"
End
 temperature > 81
                                      then do
   Weather = "hot"; Like = "yes!"
End
Say "The temperature now is "temperature,
    " and the weather is "Weather"."
Say "Do I like this weather? "Like
```

In the above example, there are two short instructions in every If-then-do group also. But since we stacked them on one line, we saved 6 lines in the program. That made this routine more compact, and we can therefore see more of the program on one screen. This technique, more importantly, did not compromise the appearance or readability of this code.

Sigl

Purpose:	Special TSO variable that contains the line number of the last instruction that caused a jump to a label.
Usage:	This variable is very useful for tracing and debugging purposes. It can tell you exactly where you came from, without having to "drop breadcrumbs".
Example:	The following exec: Say "Hello. I am line 3" Say "Hello. I am line 4" Call ProcOl Say "Hello. I am line 6" Signal TagOl TagOl: Say "Hello. I am line 9; Sigl="Sigl Exit ProcOl: Say "Hello. I am line 13; Sigl="Sigl Return
	Will display: Hello. I am line 3 Hello. I am line 4 Hello. I am line 13; Sigl=5 Hello. I am line 6 Hello. I am line 9; Sigl=7

Sign

Purpose:	Return the arithmetic sign of a number
Type:	Rexx Function
Syntax:	Result = sign(number)
Usage:	This function returns a 1 if the number is positive, and a negative 1 if it is negative. It will return a zero if it is neither (a zero is considered neither positive or negative).
Example 1:	<pre>Number = -3 Say "The sign of this number is " sign(Number) Number = -1 Say "The sign of this number is " sign(Number) Number = 0 Say "The sign of this number is " sign(Number) Number = +1 Say "The sign of this number is " sign(Number) Number = 2 Say "The sign of this number is " sign(Number) Number = +3 Say "The sign of this number is " sign(Number) The above example yields the following displays: The sign of this number is -1 The sign of this number is 0 The sign of this number is 1 The sign of this number is 1 The sign of this number is 1</pre>

Signal

Purpose:	To unconditionally branch (transfer control) to another part of the program.		
	This instruction lends to "spaghetti code", and should therefore be used only when it would make the code clearer. "Bailing out" of a complicated routine is a good example.		
Type:	Rexx Instruction		
Example:	Signal Endit /* An error has occurred */		
	Endit: Say "Program ending now due to error" Exit		

Note: I have found the signal instruction to be unreliable in some cases. In these cases, for some reason, the signal statement simply fails to function. When this happens, the use of switches to control processing is recommended. An example follows.

ErrorSw = 'N'	/* Initialize the error switch $*$	/
Call Proc01	/* Perform routine 01 */	
If ErrorSw = 'N'	then	
Call Proc02	/* Perform routine 02 */	
If ErrorSw = 'N'	then	
Call Proc03	<pre>/* Perform routine 03 */</pre>	

If an error occurred in either Proc01 or Proc02, instead of performing a "Signal" to the end of the program, you could simply set the error switch to 'Y', and then conditionally perform the rest of the program routines upon return.

Signal On

Purpose: Turn on error trapping.

Syntax: Signal On *condition*

See "Trapping Errors" in the **Environment** section of this manual for a discussion of this instruction.

SourceLine

Purpose:	Return the text of the program source				
Type:	Rexx Function				
Syntax:	Result = SOURCELINE(number)				
Usage:	This function will return the actual program text of the line number supplied.				
Example 1:	<pre>1 /* Test1 - Rexx Example Program */ 2 Say "Hello World #1" 3 Say "Hello World #2" 4 Say "Hello World #3" 5 Say "Hello World #4" 6 Say "Hello World #5" 7 Say "Hello World #6" 8 Say "Hello World #7" 9 Say "Line three of the program is "SourceLine(3) The above example will display the following: Hello World #1 Hello World #2 Hello World #3 Hello World #4 Hello World #5 Hello World #5 Hello World #7 Line three of the program is Say "Hello World #2"</pre>				

Space

Purpose:	Adds blanks to or removes blanks from between words in a string.				
Type:	Rexx Function				
Syntax:	<i>NewString</i> = SPACE(<i>OldString,quantity</i>) where <i>NewString</i> is the result of putting <i>quantity</i> blanks between every word in OldString.				
Usage:	If <i>quantity</i> is "0", this function will <i>remove</i> all blanks from the string. The function does not take into consideration how many spaces are already between words. It sets the string to the quantity you supply. Therefore, this instruction can be used to nicely format a sentence.				
Example 1:	<pre>Greeting = "Merry Christmas to one and all" NewGreeting = space(Greeting,0) Say NewGreeting NewGreeting = space(Greeting,1) Say NewGreeting NewGreeting = space(Greeting,2) Say NewGreeting NewGreeting = space(Greeting,3) Say NewGreeting This exec will display the following: MerryChristmastooneandall Merry Christmas to one and all Merry Christmas to one and all</pre>				

Stack

Purpose:	Serve as an "input queue" for TSO commands in a Rexx Exec					
Usage:	The Stack (or TSO stack, as it is more commonly called) is a storage area used to hold TSO commands that are about to be executed. These TSO commands were moved into the stack by either an individual keying them in at the terminal, or by a Rexx program.					
	When a Rexx exec needs information, it first looks for it on the stack. If the stack is empty, TSO will prompt the user (see example 1).					
	If you wish to read TSO commands directly, and bypass the stack, use <i>Parse External</i> .					
	More than one TSO stack can be created. The number of TSO stacks is limited only by the core available. Only the current TSO stack, though, is the one that is the subject of operations.					
	The TSO stack can be shared by subroutines and by called programs.					
	If you read information into the stack and leave it there, then after your Rexx exec ends, TSO will try to execute each item in the stack (see example #2).					
	Several commands operate on or manipulate the stack:					
	Push Adds items to the stack					
	Pull Removes items from the stack					
	Queue Adds items to the stack					
	NewStack Establishes a new stack DelStack Deletes the current (newest) stack					
	DelStackDeletes the current (newest) stackExecIOReads/writes a file or array into/from the stack					
	Each of the items above is documented in this manual in detail as their own subjects.					
Example 1:						
	1 NewStack					
	2 Push "Hello #1" 3 Pull Answer1					
	4 Say "I just learned" Answerl					
	5 Pull Answer2					
	6 Say "I just learned" Answer2					
	In this example,					
	1 Establishes a new stack					
	2 Puts the phrase "Hello #1" onto the stack3 Gets (and removes) that phrase from the stack					

4 Displays I just learned HELLO #1 5 Prompts the user for more input, since the stack is now empty 6 Displays whatever the user just typed in.

Example 2:

NewStack Push "Hello #1" Push "Hello #2" Push "Hello #3" Push "Hello #4" Push "Hello #5" **This example will display the following:** COMMAND HELLO NOT FOUND COMMAND HELLO NOT FOUND COMMAND HELLO NOT FOUND COMMAND HELLO NOT FOUND COMMAND HELLO NOT FOUND

Strip

Purpose:	Removes leading or trailing spaces from a string.				
Type:	Rexx Function				
Syntax:	<i>NewString</i> = STRIP(<i>OldString,option</i>) where <i>NewString</i> is the result of removing blanks from <i>OldString</i> based on the setting of <i>option</i> .				
Usage:	The function will remove from the string: Leading blanks (option = "L"), Trailing blanks (Option = "T"), or Leading and Trailing blanks (Option = "B")				
Example 1:	<pre>Greeting = " Happy New Year to you " NewGreeting = Strip(Greeting,"L") Say NewGreeting NewGreeting NewGreeting NewGreeting = Strip(Greeting,"B") Say NewGreeting This exec will display the following results: Happy New Year to you Happy New Year to you</pre>				

SubCom

Purpose:	Poll TSO to see if a particular environment is available.				
Type:	TSO command				
Syntax:	Subcom environment				
Usage:	This command can be used to test to see if an environment is available before issuing commands to it. For example, before you invoke the ISPF editor on a dataset, it may be a good idea to first check to see if the system has ISPF available (although this would be a good assumption).				
	This is the strongest reason that I could come up with for using this command, which probably demonstrates why I have never used it in any of my execs. In certain situations, there may indeed be a good reason to use it.				
See also:	Address				
Example:	"SubCom TSO" If RC = 0 then Say "TSO is available" Else Say "TSO is not available; RC=" RC "SubCom ISPF" If RC = 0 then Say "ISPF is available" Else Say "ISPF is not available; RC=" RC "SubCom Junk" If RC = 0 then Say "Junk is available" Else Say "Junk is not available; RC=" RC "SubCom ISPEXEC" If RC = 0 then Say "ISPEXEC is available" Else Say "ISPEXEC is not available; RC=" RC "SubCom ISREDIT" If RC = 0 then Say "ISPEXEC is not available; RC=" RC "SubCom ISREDIT" If RC = 0 then Say "ISREDIT is available" Else Say "ISREDIT is not available; RC=" RC "SubCom CMS" If RC = 0 then Say "CMS is available" Else Say "CMS is not available; RC=" RC The above exec will display the following: TSO is available ISPF is not available; RC= 1 Junk is not available; RC= 1 ISPEXEC is available ISREDIT is available CMS is not available; RC= 1				

SubStr

Purpose:	This is a Rexx built-in function that will return a portion of a string or variable.
Type:	Rexx Function
Syntax:	 var = SUBSTR(string,begin,length) var Any variable name string The object string (can be a literal also) begin The beginning position of the string you wish to refer to length Then length of the string you wish to refer to
Example:	Section = substr(alphabet,4,5) Where alphabet is a string containing all of the letters of the alphabet After this instruction executes, the variable SECTION will contain "DEFGH"

SubWord

Purpose:	Returns a subset of a sentence			
Type:	Rexx Function			
Syntax:	<i>NewString</i> = SUBWORD(<i>OldString,start,quantity</i>) where <i>NewString</i> is the result of copying <i>quantity</i> words from <i>OldString</i> , starting at word number <i>start</i> .			
Usage:	Extract a fixed number of words from a sentence.			
Example 1:	<pre>Phrase = "Fourscore and seven years ago, our fathers" Extract = SUBWORD(Phrase,2,3) Say Extract Extract = SUBWORD(Phrase,7,3) Say Extract This example will display the following: and seven years fathers</pre>			

Symbol

Purpose:	Tells if a character string is a variable, literal, or neither				
Type:	Rexx Function				
Syntax:	<i>Result</i> = SYMBOL(<i>charstring</i>)				
Usage:	 According to "the book", this function will test a character string, and return one of the following: VAR If the character string is a valid variable name LIT If the character string is a valid literal BAD If neither of the above I have found that this function will return only "LIT" or "BAD", based on whether the supplied character string can comprise a valid variable name. 				
Example:	<pre>Result = SYMBOL(Myname) Say Result Myname = 4 Result = SYMBOL(Myname) Say Result Result = SYMBOL("**") Say Result Will display: LIT LIT BAD</pre>				

SYSDSN

Purpose: Return the status of a datasetname

Type: TSO external function

Syntax: *Result* = SYSDSN(datasetname)

Usage: This function can tell you whether a dataset appears in the catalogue, whether a member name appears in a PDS, etc. It is not quite as comprehensive as LISTDSI.

Consult the following chart for possible results.

Result	Reason
DATASET NOT FOUND	The datasetname was not in the catalogue
ERROR PROCESSING REQUESTED	
DATASET	
INVALID DATASETNAME	The datasetname was invalid: Length > 44
	chars, invalid chars, etc.
MEMBER NOT FOUND	Looking for a member of a PDS, but it
	was not found
MEMBER SPECIFIED, BUT DATASET	Looking for a member of a PDS, but the
IS NOT PARTITIONED	dataset is not a PDS
MISSING DATASETNAME	SYSDSN(): no datasetname supplied
OK	Disk dataset, in catalogue
PROTECTED DATASET	
UNAVAILABLE DATASET	
VOLUME NOT ON SYSTEM	Tape dataset, in catalogue

See also: LISTDSI

SYSVAR

Purpose:	Return	information	about	the system

Type: TSO external function

Syntax: *Result* = SYSVAR(infoRequest)

Usage: This function can tell you the current TSO user signed on to the system, the name of the logon proc being used, and many other things. Consult the following chart for a list.

InfoRequest	Description
SYSCPU	The number of CPU seconds used in this TSO session so far
SYSENV	Thre environment you are currently executing in:
	FORE for foreground; BACK for background (via JCL)
SYSHSM	This will be the HSM release number. If HSM is not available, this will
	be blank.
SYSICMD	The name of the command or Rexx exec
SYSISPF	ACTIVE if the ISPF dialogue manager is active. Test this variable in
	your exec if it depends on ISPF services being available.
SYSLRACF	RACF level, or spaces if not available
SYSLTerm	Number of lines available on the terminal screen.
SYSNEST	YES if executed from another exec or CLIST; NO if executed from
	TSO.
SYSPCmd	The most recently-executed TSO command from this exec. It will be
	EXEC if there was none.
SYSPREF	The prefix that TSO puts in front of unqualified datasetnames.
SYSPROC	The name of the procedure that was used to log on to TSO
SYSRACF	AVAILABLE, NOT AVAILABLE, or NOT INSTALLED
SYSSCmd	The most recently-executed TSO sub-command. This is "the book"
	explanation, but I find it to be always blank.
SYSSRV	How many SRM units were used so far
SYSTSOE	TSO/E level
SYSUID	The TSO UserID of the currently-logged on user
SYSWTerm	Number of columns available on the terminal screen. This is
	LINESIZE+1

Time

Purpose: This is a REXX built-in function that will provide you with the current time, in a variety of different formats.

Type: Rexx Function

Syntax: Result = Time(option) Based on the specification of the Options below, "result" will contain the time in the corresponding format, if the current time was 1:05pm (plus a few seconds).

Option	Meaning	Format	Example
(blank)	normal (same as 'N')	hh:mm:ss	13:05:13
С	Civil	hh:mm xm	1:05pm
Е	Elapsed (seconds and microseconds)	ssssssss.mmm	111111.222222
		mmm	
Η	hour, 24-hour format	hh	13
L	long	hh:mm:ss.dddd	13:05:13.090191
М	Number of minutes since midnight	nnnn	785
Ν	normal	hh:mm:ss	13:05:13
R	Reset elapsed time		0
S	Number of seconds since midnight	nnnnn	47113

If you use an unsupported option, for example "A", you will see an error message similar to the following:

5 +++ Say "The time now is " Time(A)

Error running AskTime, line 5: Incorrect call to routine

This command can also be used for measuring elapsed time. The first time this command is issued with either the 'E' or 'R' option, the elapsed time counter is started. Every subsequent issuance of the command with either of these options will return the elapsed time since the first issuance of Time('E') or the last issuance of Time('R'). Issuing the command with option 'R' will reset the elapsed time counter, but only *after* it returns the elapsed time.

```
The following example demonstrates the use of elapsed time.

Dummy = Time(E) /* Start time */

Say "I am waiting for you to hit enter!"

Pull Answer

Duration = Time('E')

Say "Point1:" Duration "seconds!"

Duration = Time('E')

Say "Point2:" Duration "seconds!"

Duration = Time('R')

Say "Point3:" Duration "seconds!"

Duration = Time('E')

Say "Point4:" Duration "seconds!"
```

Say "Point5:" Time('E') "seconds!"

This exec will display something like this: I am waiting for you to hit enter! Point1: 1.200962 seconds! Point2: 1.203493 seconds! Point3: 1.205070 seconds! Point4: 0.001185 seconds! Point5: 0.002150 seconds!

Trace

Purpose:List instructions as they are executed; variables as they are setType:Rexx FunctionSee "Debugging" for a discussion on this subject

Translate

Purpose:	Convert characters to other characters
Type:	Rexx Function
Syntax:	Result = TRANSLATE(ObjectString,String2,String1)
Usage:	Convert all occurrences of <i>ObjectString</i> that appear in <i>String1</i> to the corresponding character in <i>String2</i> .
Example 1:	I find this a difficult command to conceptualize, to explain, or to remember, so a very detailed example is necessary here.
	Say TRANSLATE ("ABCDEFGHIJ", "1234567890", "DAVE") Would result in: $_{2BC14FGHIJ}$ Because: String1 = "DAVE" String2 = "1234567890" ObjectString = "ABCDEFGHIJ" Result = "2BC14FGHIJ" In <i>ObjectString</i> , the first character, <i>A</i> , appears in <i>String1</i> . So that <i>A</i> in <i>ObjectString</i> is replaced by 2, which is the character in <i>String2</i> that corresponds to the character in <i>String1</i> . The next character in ObjectString does not appear in String1, so it is not converted. The same applies to the third. The fourth character in <i>ObjectString</i> (D), however, does appear in <i>String1</i> . So that <i>D</i> in <i>ObjectString</i> is replaced by <i>1</i> , which is the character in <i>String2</i> that corresponds to the character in <i>String1</i> . To visualize how this command works, and how to make it work for you, just lay <i>String1</i> on top of <i>String2</i> , like I have here.

Example 2: In this scenario, it turns out that the English teacher mistakenly gave the class the wrong test: it was one grade level too high. So now, she wants to push everyone's grade up one notch, instead of making everyone re-take the test. First, let's lay out String 1 and String 2: String1 = 'BCDF' String2 = 'ABCD' Then code the Rexx exec, as follows: OldGrades = "BBCCBDFDDFD" NewGrades = TRANSLATE(OldGrades, "ABCD", "BCDF") Say "The old grades were" OldGrades Say "The new grades are " NewGrades

which will result in:

The old grades were BBCCBDFDDFD The new grades are AABBACDCCDC

Trunc

Purpose:	Return a number with a specified number of decimal places
Type:	Rexx Function
Syntax:	<i>NewNumber</i> = TRUNC(<i>Number</i> , <i>DecimalPlaces</i>) where <i>NewNumber</i> is <i>Number</i> with <i>DecimalPlaces</i> decimal places.
Usage:	This command could have been called <i>Decimal Places</i> , because that applies more than <i>Trunc</i> . The command will add or remove positions based on the specification of decimal places.
Examples:	Say Trunc(1.12345,0) Say Trunc(1.12345,4) Say Trunc(1,4) Will display: 1 1.1234 1.0000

Purpose:	Upper Convert a character string to upper case
Type:	Rexx Instruction
Syntax:	UPPER variable1 {variable2} {variable3}
Examples:	fname='George'; lname='Bush' Upper fname lname Say lname ',' fname /* displays "BUSH , GEORGE" */
See also:	Parse Upper Arg

UserID

Purpose:	Return the TSO UserID of the resource who is currently logged on to the system
Type:	Rexx Function
Usage:	This is commonly used to determine access priviledges.
Examples:	Say "Your userID is" UserID()
	Could display: Your userID is DGRUND01

Value

Purpose: Returns the contents of a variable after resolving it. The main purpose for this function is to resolve a dynamically-created variable.

Type: Rexx Function

Syntax: NewVar = VALUE(variable)

Usage: There is a subtle difference between using VALUE(variable) and just the variable itself. Value will convert the contents of a variable to upper case while resolving it.

Simple example:

```
Name = "Dave"
Say "My name is "value(Name)
Say "My name is "Name
```

The above exec will display: My name is DAVE My name is Dave

Example of resolving a dynamically-created variable.

In one particular Rexx exec, I create ten arrays, named Array01, Array02, ... Array10. We wish to perform the same processing on each array, so we use a subroutine, or what is more commonly known as a procedure.

Example pending

Variables

Purpose:	To retain values for use later in the program. A variable can hold any type of value: character, numeric, hex, binary, etc.	
Syntax:	A variable must start with a character (never a number), and certain special characters. The rest of the variable can contain alphabetic characters, numbers, and certain special characters.	
	Some special characters that can appear in a variable name are as follows: @ # \$!	
	Some special characters that can <i>not</i> appear in a variable name are as follows: % &	
	For any other special characters, you're on your own. Try it out; it can't hurt.	
	A variable name can be up to 250 characters long.	
Usage:	A variable in Rexx does not get declared. It is assigned a value by using it on the left side of an assignment statement, or with the use of certain Rexx instructions. A variable is not a variable until it is given a value. Note that until a variable is given a value, it is a literal. If a variable's value is removed (with the "Drop"), it is then converted back to a literal.	
	If you happen to see a variable name appear in your output unexpectedly, there is a good chance that you misspelled either it, or the one that you initialized.	
Example:	My_name = "John Smith"	

Variables, Compound

Purpose: To act as a variable, with an added benefit. The same variable name can be used to contain any number of similar values. This is a very powerful feature of Rexx, and is very simple to implement. This feature is commonly used to construct an array. Syntax: Same as regular variables, but with a period and a suffix added to the end. Usage: Simply assign a value to the nth element of the array. The "0th" element is used to contain the number of elements in the array. Example: The following excerpt from a Rexx exec: Name.1 = "Mary" Name.2 = "Joe" Name.3 = "Alice" Name.4 = "Smokey" /* Establish no. of elements */ Name.0 = 5Say "There are "name.0" elements in this array" Do I = 1 to Name.0 Say Name.I End Will yield the following results: Mary Joe Alice Smokey NAME.5

Verify

Purpose:	Tells whether certain characters are contained in a given chracter string	
Type:	Rexx Function	
Syntax:	<i>Result</i> = VERIFY(<i>FindString</i> , <i>ObjectString</i>) <i>Result</i> is the first position of <i>FindString</i> that does not appear in <i>ObjectString</i> .	
Usage:	If <i>Result</i> is zero, then all of <i>FindString</i> appears somewhere in <i>ObjectString</i> . Both strings are case-sensitive: a lower-case letter will not match an upper-case, and vice-versa.	
Example:	<pre>Say Verify('I','TEAM') Say Verify('Scienc',"ConSciencious") Say Verify('fat',"indefatigable") Say Verify('hillary','hilarious') Will display: 1 (There is no "I" in "TEAM") 0 0 7</pre>	

Word

Purpose:	Returns the nth word of a string.	
Type:	Rexx Function	
Syntax:	Result = WORD(phrase, n) Result is the <i>n</i> th word of <i>phrase</i> .	
Usage:	If n is greater than the number of words in the phrase, result will contain blanks. If n is zero, the function will err out.	
Example:	<pre>Say Word("Merry Christmas and Happy New Year",2) Say Word("Merry Christmas and Happy New Year",7) Say Word("Merry Christmas and Happy New Year",0) Will display: Christmas 3 +++ Say Word("Merry Christmas and Happy New Year",0) Error running Test1, line 3: Incorrect call to routine</pre>	

WordIndex

Purpose:	Return the character position of a word in a string	
Type:	Rexx Function	
Syntax:	Position = WORDINDEX(string,n) where <i>Position</i> is the character number of the <i>n</i> th word in <i>string</i> .	
Usage:	This function will return the character position where a particular word starts in a string.	
Example:	Answer = WordIndex("Merry Christmas and Happy New Year",5) Say Answer Would display 27 The 5th word of the string is New, which starts at character position number 27.	

WordLength

Purpose:	Return the length of a word in a string	
Type:	Rexx Function	
Syntax:	Answer = WORDLENGTH(string,n) where Answer is the length of the <i>n</i> th word in <i>string</i> .	
Usage:	This function returns the length (number of characters) of a word in a string.	
Example:	Answer = WordLength("Merry Christmas and Happy New Year",5) Say Answer Would display 3 The 5th word of the string is "New", whose length is 3.	

WordPos

Purpose:	Return the position of a word or phrase in a string	
Type:	Rexx Function	
Syntax:	Answer = WORDPOS(phrase, string) where Answer is the length of the <i>n</i> th word in <i>string</i> .	
Usage:	This function returns the word position of a phrase in a string.	
Example:	Answer = WordPos('and Happy',"Merry Christmas and Happy New Year") Say Answer Would display 3	

Words

Purpose:	Returns a count of the words in a string	
Type:	Rexx Function	
Syntax:	Answer = WORDS(string)	
Example:	Answer = Words("Merry Christmas and Happy New Year") Say Answer Would display 6	

XRange

Purpose:	Return a string of characters between two characters in the ASCII character set.
Type:	Rexx Function
Syntax:	Result = XRange(startchar,endchar) startchar-The first ASCII character that will be returned. The default is low-value (X'00'). endchar- The last ASCII character that will be returned. the default is high- value (X'FF').
Usage:	This function will return all of the characters in the ASCII Character set between <i>startchar</i> and <i>endchar</i> , inclusive. If <i>startchar</i> is greater than <i>endchar</i> , then the string that is returned will wrap around through the beginning.
Example 1	The following example will not return the letters in the alphabet as a string. This is unfortunate, because the function would be a little more useful if it considered only valid characters. Alphabet = XRange('A','Z') Say Alphabet The reason for this is that the leters of the alphabet do not appear continuously in the ASCII character set. What would be returned would be the ASCII characters represented by X'C1' through X'E9', inclusive: ABCDEFGHIJKLMNOPQRSTUVWXYZ
Example 2	The following example will return the alphabet. Alphabet = XRange('A','I')XRange('J','R')XRange('S','Z') Say Alphabet

X2C

Purpose:	Converts a hexadecimal string to character
Type:	Rexx Function
Syntax:	CharString = X2C(hexstring)
Example:	Answer = X2C('C4C1E5C560F1F6F1F6') Say Answer Would display Dave-1616

X2D

Purpose:	Converts a hexadecimal string to decimal
Type:	Rexx Function
Syntax:	Number = X2C(hexstring)
Example:	Answer = X2D('FF') Say Answer Would display 255
	Answer = X2D('FFFF') Say Answer Would display 65535

Instructions Not Covered

Certain instructions, commands, and functions are seldom, if at all, used in applications. These are used by system administrators and system programmers. These instructions, commands, and functions are listed here. Why are they even mentioned, if we are not going to document them?

They are listed, for the most part, let you know (and to remind me) that they are indeed available, if we want to use them or learn more about them. Documentation of these instructions, commands, and functions is beyond the scope of this manual. Check the appendix for additional sources of documentation.

DropBuf	Delete a data stack buffer	
ExecUtil	Control Rexx processing options for the current Rexx environment	
MakeBuf	Add a buffer to the data stack	
Options	This instruction is used for DBCS (Double-Byte Character Set) character and data operations support.	
Qbuf	determine the number of data stack buffers that exist	
Qelem	Determine the number of data stack elements that exist	
Storage	Retrieve a number of bytes from a main storage address, or store a number of bytes into a main storage address.	

Section II -A Starter Rexx Tutorial

Follow this tutorial by keying in the example Rexx execs and reading the associated commentary. If your results are not identical to those of the tutorial, try to find out *exactly* why. Each example builds on the previous ones, so it is important that you understand each before you move on.

/* Rexx Exec Tutorial #1 */ Say "Hello World"

This is one of the shortest Rexx execs ever written. All it does is display the famous programmer's primer message.

/* Rexx Exec Tutorial #2 */
Say "What is your name?"
Pull Answer
Say "So, your answer is " Answer". That is swell!"

This exec will ask you your name, and if you reply, it will echo it back, something like this: So, your answer is JOHNNY. That is swell!

/* Rexx Exec Tutorial #3 */ Say "What is your name?" Pull Answer

Say "So, "Answer", how old are you?" Pull Age AgeIndays = Age * 365 Say "If you didn't lie to me, you are about" AgeInDays "days old."

This exec will ask you your name, and then perform a calculation. Notice that I used an apostrophe within a string that was enclosed in quotation marks. The exec's last display would look like this:

If you didn't lie to me, you are about 8030 days old.

From here, the possibilities are endless. Rather than waste your (and my) time by making you go through endless and pointless exercises, I will stop here, and let you get started with playing with some ideas of your own. Just remember: have fun!

Section III - Rexx Examples

I believe strongly in examples. No matter what someone is trying to say, it is clearer if it can be illustrated with a good example. A person can then glean an interpretation from that example.

The easiest way to write a Rexx exec is to take one that exists, and tailor it for your own use. Remember that like with any programming language, if you copy someone's source code verbatim, it's not ethically cool to put your name on it. If you use a major portion of source code that is provided to you for free, it is only fair to at least give credit to the author somewhere in your program. All of these examples were written by David Grund Sr., and are free to use.

The examples provided here vary in purposes, but can be tailored to most specific needs that you have. They don't necessarily demonstrate the *best* way to write a Rexx exec in all cases. They *do*, however, demonstrate different techniques.

In some cases, some of the execs depend on data from ISPF libraries. That data is not included.

Disclaimer: All examples are provided for the sake of example only. There is no guarantee that these work as desired, or are entirely bug-free. You are free to, and encouraged to, develop and improve any or all of these examples.

Please respect an author's inventiveness and hard work. Since Rexx execs are distributed with the source, if you publish any new Rexx execs that you created using an existing one as a basis, you are requested to at least credit the author.

The examples provided here are as follows:

ALLOCEIO	Allocate O/P dataset; write Rexx array to it
CAPTSO	Capture TSO command output
CHGBLKC	Insert a COBOL change block
CHGDATA	Modify a data file
CHGSTEP	Change steps in JCL
COMMANDS	List available commands
COMPCO	Compare two files of order numbers
COMPDS	Compare two sequential datasets
COMPPDS	Compare two PDS's
DD	Add a DD Statement
DELDUPS	Delete duplicate records
DURATION	Time an EXEC
FIXJCL	Fix Job Control
FX	File name cross-reference
HD	Hex Dump
INIT	Establish my TSO environment
INITSPF	Establish my ISPF environment
JOBCARD	Create a jobcard
JUMBLE	Display all combinations of letters
LA	List TSO allocations
LISTDSI	List dataset information
LOTTERY	Pick lottery numbers
LPDSIX	List a PDS Index to a Sequential File
PROCSYMS	Perform symbolic substitution
PTS	PDS-to-Sequential; member name is prefix
PTS2	PDS-to-Sequential; member name is inserted
REXXMODL	Rexx Exec Model
SCALE	Display a Scale
SDN	Sorted Directory w/Notes; directory annotator
SHOWDUPS	Show duplicate records
STACK	Start another ISPF session
TIMEFMTS	Show all time formats
TIMETOGO	Display time until an event

ALLOCEIO - Allocate O/P dataset; write array to it

This is a code snippet that will allocate a TSO dataset, and then write a Rexx array to that dataset. The TSO dataset is deleted first, in case it already exists.

"Delete "MapDSN
"Allocate DD(FiCvtDS) DA("MapDSN") new space(1 1) tracks",
 "LRECL(80) Block(6160) recfm(f b) RETPD(0)"
"ExecIO" MapArray.0 "DiskW FiCvtDS (STEM MapArray. FINIS"
"Free DDNAME(FiCvtDS) DA("MapDSN")"

CAPTSO - Capture TSO command output

Using this exec, you can capture the output from just about any TSO command. The purpose, of course, is to dump it into a dataset and edit it.

```
/* CapTSO - Capture TSO Output - Rexx Exec */
/* Written by Dave Grund */
Dummy = OutTrap("output_line.","*")
"LISTd 'GRUND.ASSEMBLY.DATA' m"
NumLines = OutPut_Line.0
Say NumLines "lines were created"
Dummy = OutTrap("OFF")
"Delete CAPTSO.List"
"Allocate DD(CapTSO) DA(CAPTSO.List) new space(15 15) tracks",
                "LRECL(80) Block(6160) recfm(f b) RETPD(0)"
"ExecIO" OutPut_line.0 "DiskW CapTSO (STEM OutPut_Line. FINIS"
"Free DDNAME(CapTSO) DA(CAPTSO.List)"
ADDRESS "ISPEXEC" "EDIT Dataset(CAPTSO.List) "
```

CHGBLKC - Insert a COBOL change block

This Rexx exec is an ISPF edit macro, used to insert a program modification comment block into a program. By using this exec, you can make the comment block will look the same for every program, hence an increase in productivity. This technique, of course, can be used for any language. I have created one for Easytrieve and another for Assembler.

```
/* ChqBlkC - Insert COBOL Change Block - ISPF Edit Macro (REXX EXEC) */
ADDRESS "ISREDIT" "MACRO PROCESS"

  11 1
```

CHGDATA - Modify a data file

This exec is used to modify a data file. It reads a data file into core (an array), modifies it (with hard-coded instructions), and then writes it back out. This is an exec that is tailored for use each time it is used.

```
*/
/* ChgData - Change a File - REXX Exec
                                      */

CHGSTEP - Change steps in JCL

When you have religiously numbered the steps in a job stream, and find that you have to insert a few, especially toward the *beginning*, your neatly-sequenced step names are compromised.

This Rexx exec will "quickly" renumber the steps so they are back in sequence and incremented by 10.

Here, you are creating the list of TSO commands that you will use to ultimately make the changes. Creating a TSO command set is less stressful than making the changes one-by-one. This way, you don't have to remember where you left off, and you can use ISPF's editor to mass-produce the change statements.

COMMANDS - List available commands

This is a very simply Rexx exec, but is very useful. I write so many little Rexx execs that sometimes I forget what the names of them are. So every time I write a new Rexx exec, I update a Rexx exec called "Commands". Then, when I need to remember a command name, I simple execute the "Commands" command, and it produces a list for me.

This is provided as a suggestion more than as an example.

COMPDS - Compare two sequential datasets

This exec will call IEBCOMPR to compare two datasets. You don't get a comprehensive and detailed listing of differences. Instead, you get notification as to whether the two datasets contain exactly the same data- a check that is required in a parallel test.

```
/* Compare - Compare Two Datasets - Rexx Exec */
/* Written by Dave Grund
                                               */

COMPDSE – Compare Two Sequential Datasets - Enhanced

This exec will compare two sequential datasets, line-for-line, and report diferences. Neither file is assumed to be in any kind of sequence. This differes from COMPDS in that it does not call IEBCOMPR; it does the compares internally.

The best thing about this tool is that it can be copied and modified for specialized file compare needs.

```
/* COMPDSE - Compare Two Datasets - Enhanced
                                                               REXX */

ConcatL - Concatenate Libraries

This command will concatenate a library to a current DDName's allocation.

If you wanted to add your Rexx Exec library to an existing SYSEXEC allocation, you could do it two ways:

- 1) You could free SYSEXEC, and then reallocate all necessary libraries, including your own. But that would make you dependent upon someone in Systems to tell you when the normal allocation (all necessary libraries) changes.
- 2) You could simply add your library to the current concatenation, using this example. This way, if the "necessary library" sequence changes, you will not be affected. Your library will always be concatenated to that set.

```
/* ConCatL - Allocate a library to an exiting concatenation REXX */
Arg SearchDD LibToAdd
LibToAdd = "'"LibToAdd"'"
                             /* Add some quotes */

DURATION - Time an EXEC

This Rexx exec can be modified to time the processing of a command. It's a good idea to do this is some of the longer-running execs, or to brag about how fast your exec can accomplish something!

FindMem - Find a Member in a Concatenation

This Rexx exec will search a concatenated set of libraries for a specific member name. This is useful for when you want to know exactly which library an ISPF panel or a Rexx Exec is being executed from.

This command can also be executed in batch to look for copybooks or load modules in a concatenation.

```
/* FindMem - Find a Member in a Concatenation REXX */

FixJCL - Fix Job Control

FixJCL is a Rexx exec that will read a set of Mainframe JCL, and make certain format changes.

Granted that these format changes are to personal style and specifications: it puts the datasetname on the first line, the disposition parameters on the second line (unless they are short), the space parameters together on the next line, the DCB parameters on the next, and anything else on the last.

The beauty of this exec is that it parses the JCL, and isolates just about every "common" JCL field, so if you didn't want to create finished, or "fixed" JCL, you could do whatever processing you wanted. Additionally, the code is all there, so you could make any desired enhancements.

The exec first reads the JCL into an array, parses and identifies it, and then creates a file of fields. The code to catalogue this particular file has been commented out, but for testing or development, you would want to open this code back up.

That array is then read, and the final JCL file is created.

Please note that the objective of this exec is twofold: to present a usable tool, and to provide the code to enhance the tool. There is a lot of room for improvement in this particular tool. It isn't meant to be a finished and shiny product. It is meant to accomplish something very useful, and allow the user to make any desired improvements or enhancements to something that has a good, solid base.

The code, in its entirety, follows: /* FixJCL - Create a Fixed File of	JCL - REXX Exec	*/
ARG IPDSN Call Proc01 Call Proc10 Call Proc30 Call Proc40	/* Program initialization /* Parse the JCL /* Write the control card array /* Write the fixed JCL	* / * / * /

SDN - Sorted Directory w/Notes: directory annotator

This is a handy ISPF macro that I wrote to keep track of what I have in my PDS's. This command will create and maintain a member called "@LIST", which contains a oneliner about each member in the PDS. Hopefully, this member will always be the first in a PDS.

Unfortunately, this command can be invoked only while you are editing a member of the PDS that you wish to annotate.

```
/* SDN - REXX EXEC
                               */
/* Sorted Directory w/Notes - Edit Macro */
/* Written by Dave Grund */
/* Changed 7/27/95- restore the TSO Profile prefix before ISPF
                                                   */
/* edit is invoked, instead of after the command is complete
                                                   */

Section IV - The Rexx Environment

This section of the manual describes the following Rexx features:

- 1. Establishing your Rexx environment
- 2. Using Rexx with ISPF
- 3. Using Rexx in the background (batch jobs)
- 4. Debugging your Rexx program
- 5. Trapping Errors
- 6. Examples

Establishing your Rexx environment

This procedure has gone through several variations.

Previously, you had to research to see what was currently allocated to SYSPROC (for Clists) or SYSEXEC (for Rexx execs). Then you had to free the DDName, allocate your exec library to SYSPROC, and then reallocate all of the system libraries that were previously allocated to it. The problem with this was that if the system administrators responsible for the concatenation of your procedure libraries changed the list of files allocated to that DDName, you would not have that new list available to you.

Some shops started to write their logon procedures so you could pass it the name of a library that you wanted to allocate in front of (or in back of) the list of system exec or clist libraries. There was a lot of room for error in this method.

IBM has supplied us with a solution to this dilemna. It is called ALTLIB.

Now, to establish your own personal Rexx exec library (a library from which all of *your* execs will be called), perform the following steps:

• Create a PDSE whose last level is EXEC.

You can create a PDSE through ISPF 3.2, then option M. You can also use the following command:

```
Address TSO
"Free Fi(NEWDA)"
"delete REXX.EXEC"
"Alloc Fi(NEWDA) DA(REXX.EXEC) new space(15 1) dir(1) track" ,
        "DSNType(Library)" ,
        "dsorg(PO) recfm(F b) lrecl(80) blksize(0)"
"Free Fi(NEWDA)"
```

• Populate that PDSE with your execs

Then, whenever you log on to TSO,

- Allocate DDName SYSUEXEC to that newly-created library
- "Alloc Fi(SYSUEXEC) DA(REXX.EXEC) SHR"
- Issue the ALTLIB command.
- "ALTLIB Activate User(exec)"

Using Rexx with ISPF

You can invoke the ISPF editor or browser from within a Rexx exec. Furthermore, you can run a Rexx exec upon beginning the edit of a dataset. This feature is called an ISPF edit macro.

ISPF Browser

To browse a dataset from within a Rexx exec:

ADDRESS "ISPEXEC" "BROWSE Dataset(dsn)" where

dsn is the datasetname of the file you wish to browse

ISPF Editor

To edit a dataset from within a Rexx exec:

ADDRESS "ISPEXEC" "EDIT Dataset(*dsn*) Macro(*macname*)"

where

dsn is the datasetname of the file you wish to edit *macname* is the name of the ISPF Rexx exec that will function as the ISPF macro.

ISPF Edit Macros

The purpose of an ISPF edit macro is to perform one or more ISPF edit commands on a dataset immediately after opening it for edit. If you need to do something to a dataset after it is opened for edit, an edit macro may be the way to accomplish this.

A complete dissertation of ISPF edit macros is beyond the scope of this book, but I provide enough to at least let you know how they are used in conjunction with Rexx.

An ISPF edit macro can be used to reformat or restructure data in a dataset prior to the dataset being presented to the user for editing.

The first line in an ISPF macro is one to tell the Rexx exec that it is to function as an ISPF macro:

Address "ISREDIT" "Macro Process".

Just about any ISPF editor primary command can be used in an ISPF macro. Simply precede the command with Address "ISREDIT".

This is an example of an ISPF macro that is used to edit the output of the TSO command LISTA SY ST (see the "LA" exec in the examples): /* REXX - LAE - Edit macro for LA - Rexx Exec */ /* Written by Dave Grund, April 7, 1995 */ 1 ADDRESS "ISREDIT" "MACRO PROCESS" 2 ADDRESS "ISREDIT" "EXCLUDE ALL --DDNAME 1" 3 ADDRESS "ISREDIT" "EXCLUDE ALL ' keep' 1 "
4 ADDRESS "ISREDIT" "Delete ALL X"
5 ADDRESS "ISREDIT" "C 'KEEP' '-----' word all 12"

Line 1 tells the Exec that it is an ISPF macro.

Line 2 is an ISPF command that excludes all lines where "--DDNAME" appears in column 1.

Line 3 is an ISPF command that does the same thing with a different character string.

Line 4 tells ISPF to delete all excluded lines (those that were excluded by the previous two lines)

Line 5 tells ISPF to change the all occurrences of the string "KEEP" that start in column 12 to 14 dashes.

Using Rexx in the background (batch jobs)

As long as your Rexx exec is not interactive, you should have no problem running it in the background, that is, via a job you submit from your terminal.

A good candidate for a Rexx exec that should run in the background is one that will take a lot of CPU time, or produce a lot of output. By running it in the background, you can free up your terminal to do other things.

Instead of allocating files from within your Rexx exec, you would allocate them via the JCL. You could *keep* the allocations buried within your Rexx exec, but then you will be hiding the datasetname from your user. Unless this is what you *specifically* want to do, put the DD statement for that file in the JCL, and remove the allocate step from your Rexx exec.

An example of JCL for running a Rexx exec in the background is shown:

```
1 //STEP010 EXEC PGM=IKJEFT01
2 //SYSTSPRT DD SYSOUT=*
3 //SYSTSIN DD *
4 EXEC 'GRUNDDAV.REXX.EXEC(TEST1)'
5 /*
```

Note that this JCL can be used for executing *any* TSO command, not just Rexx execs. Line 1 executes program IKJEFT01, which is the background TSO command processor. Line 2 allocates the TSO SYSOUT dataset.

Line 3 allocates the TSO SYSIN dataset

Line 4 executes the TSO command. In this case, it's an exec from my exec PDS. (Line 5 is simply the JES end-of-data statement.)

Debugging your Rexx program

If your program operates in a manner that doesn't seem quite right, and the cause is not immediately evident, it is probably time to go into debugging mode. Debugging is the process of putting code into your program to make your program tell you where it is, what it is about to do, or what it has done.

Typically, you would not leave any "active" debugging code in your production program. Instead of deleting it, you could comment it out, but if there is too much, it could detract from the readability of the program.

There are several ways to debug a Rexx exec.

One way is to put "Say" statements in strategic locations. This will tell you what paths the program is taking. Along this same line is commenting out instructions that you suspect to be causing the problems.

Another way is to use the Rexx Trace facilities.

I have always used the first method, because it is simpler, easier to "unplug", and gave me the same end result. The second method can hammer you with output that can serve more to confuse you than to help you. And to top it off, I think the Rexx Trace facilities are a little complicated. But it still warrants a short discussion, so here it is.

To interrupt your Rexx program from running, press the ATTN, or PA1 key. The program will break out of its current processing, and if there is code left to execute, the following will be displayed:

ENTER HI TO END, A NULL LINE TO CONTINUE, OR AN IMMEDIATE COMMAND+ - You have several options for a response:

1) Enter key- The program will continue running

2) **HI** (Halt Interpret)- The program will end.

3) **HT** (Halt Typing)- The program will stop displaying output.

4) **RT** (Resume Typing)- The program will resume displaying output

5) **TS** (Trace Start)- Rexx will enter Interactive Trace Mode

6) TE (Trace End)- Rexx will exit Interactive Trace Mode

Interactive Trace Mode

Interactive Trace Mode is where Rexx will display each of the lines as it executes them, prefixed by the line numbers. When it pauses for input, you can change the value of a variable, or hit Enter to continue processing.

Trapping Errors

Trapping Errors is the process of detecting certain program conditions, and then acting based on those conditions.

This facility may be used in debugging, but can also be used in a production program (but carefully).

Error-trapping instructions: Signal On *condition* Signal Off *condition* Call On *condition* Name *subroutinename*

Signal On condition

This instruction will effect a transfer of control to a designated location in the program whenever a certain condition is detected by the program. After the condition is handled, the program terminates.

Signal Off condition

This instruction will cancel the effects of a Signal On for this particular condition only.

Call On condition Name subroutinename

This instruction will cause the program to perform a call to subroutine every time the program detects a certain condition. After the condition is handled, the subroutine returns control to the next sequential instruction iun the program. The subroutine cannot return any values.

Naming a subroutine is optional.

Condition

The condition cited in the above instructions can be one of the following:

1. Syntax- Rexx encountered a syntax error in an instruction.

2. Error - A TSO or ISPF command returned a non-zero return code

3. Failure- A command that was passed to the environment has failed

4. NoValue- A variable was never given a value. Typically, this is not an error, because Rexx, by default, treats an unassigned variable as a literal.

5. Halt- The PA1/Attn key was hit.

Examples

The following Rexx exec will be used in each of the examples. For each example, the "Main processing" section of the program will be different.

```
/* Rexx program to demonstrate error-trapping */
Signal On Syntax
Call On Error Name Error_Handler
Call On Failure
Signal On NoValue
Signal On Halt
(Main processing section)
Exit
Type:
Syntax:
  Say "I am in the Syntax condition-handling routine now."
  Say "I am going to terminate the program because of this"
Exit
Error Handler:
  Say "I am in the Error condition-handling routine now."
  Say "I am going to continue processing"
Return
Failure:
  Say "I am in the Failure condition-handling routine now."
  Say "I am going to continue processing"
Return
NoValue:
  Say "I am in the NoValue condition-handling routine now."
   Say "I am going to terminate the program because of this"
 Exit
 Halt:
   Say "I am in the Halt condition-handling routine now."
   Say "I think you hit the attention key!"
   Say "I am going to terminate the program because of this"
 Exit
```

The following illustrates the output from running the above Rexx exec, causing different conditions to occur. We do this by replacing the "main processing section".

Example 1

Main processing section: Say "1) This statement is perfect, and will generate no errors." Say "2) The next statement will generate a Syntax condition" PI = 3.1416 Circumference = PI *

Displays:

This statement is perfect, and will generate no errors.
 The next statement will generate a Syntax condition
 I am in the Syntax condition-handling routine now.
 I am going to terminate the program because of this

Example 2

Main processing section: Say "3) The next statement will generate a Error condition" "Delete junk.data.set"

Displays:

3) The next statement will generate a Error condition ERROR QUALIFYING XCON620.JUNK.DATA.SET ** DEFAULT SERVICE ROUTINE ERROR CODE 20, LOCATE ERROR CODE 8 LASTCC=8 I am in the Error condition-handling routine now. I am going to continue processing (The dataset did not exist)

Example 3

Main processing section: Say "4) The next statement will generate a Failure condition" "This is not a good command"

Example 4

Main processing section:

Say "5) The next statement will generate a NoValue condition" Say "My age is " MyAge

Displays:

5) The next statement will generate a NoValue conditionI am in the NoValue condition-handling routine now.I am going to terminate the program because of this
